**NCCN Guidelines Panel Disclosures**

[Continue]
Clinical Trials: NCCN believes that the best management for any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

To find clinical trials online at NCCN Member Institutions, click here: nccn.org/clinical_trials/member_institutions.aspx.

NCCN Categories of Evidence and Consensus: All recommendations are category 2A unless otherwise indicated. See NCCN Guidelines for Breast Screening and Diagnosis.

Noninvasive Breast Cancer:
- Ductal Carcinoma In S itu (DCIS) Workup and Primary Treatment (DCIS-1)
- DCIS Postsurgical Treatment and Surveillance/Follow-up (DCIS-2)

Invasive Breast Cancer:
- Clinical Stage, Workup (BINV-1)
- Locoregional Treatment of T1–3,N0–1,M0 Disease (BINV-2)
- Systemic Adjuvant Treatment
  - Hormone Receptor-Positive HER2-Positive Disease (BINV-5)
  - Node-Negative Hormone Receptor-Positive HER2-Negative Disease (BINV-6)
  - Node-Positive Hormone Receptor-Positive HER2-Negative Disease (BINV-7)
  - Hormone Receptor-Negative HER2-Positive Disease (BINV-8)
  - Hormone Receptor-Negative HER2-Negative Disease (BINV-9)
  - Favorable Histologies (BINV-10)
  - Workup Prior to Preoperative Systemic Therapy (BINV-11)
  - Adjuvant Systemic Therapy After Preoperative Systemic Therapy (BINV-15)
  - Surveillance/Follow-Up (BINV-16)
  - Recurrent/Stage IV (M1) Disease (BINV-17)
  - Treatment of Local and Regional Recurrence (BINV-18)
  - Systemic Treatment of Recurrent or Stage IV (M1) Disease (BINV-19)

Special Considerations:
- Phyllodes Tumor (PHYLL-1)
- Paget’s Disease (PAGET-1)
- Breast Cancer During Pregnancy (PREG-1)
- Inflammatory Breast Cancer (IBC-1)
- Staging (ST-1)
Updates in Version 5.2020 of the NCCN Guidelines for Breast Cancer from Version 4.2020 include:

**BINV-L & BINV-Q**
- Preoperative/adjuvant therapy for HER2-positive disease and systemic therapy for HER2-positive recurrent or stage IV (M1) disease:
  - Footnote added: Pertuzumab, trastuzumab, and hyaluronidase-xxf injection for subcutaneous use may be substituted anywhere that the combination of intravenous pertuzumab and intravenous trastuzumab are given as part of systemic therapy. Pertuzumab, trastuzumab, and hyaluronidase-xxf injection for subcutaneous use has different dosing and administration instructions compared to the intravenous products.
Updates in Version 4.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2020 include:

BINV-Q
• Recurrent or stage IV (M1) Disease
  ▸ Added sacituzumab govitecan-hziy as an other recommended regimen for triple negative breast cancer (TNBC), with the following footnote: For adult patients with metastatic TNBC who received at least two prior therapies for metastatic disease. (BINV-Q, 1 of 7)
  ▸ Added tucatinib + trastuzumab + capecitabine (category 1) as an other recommended regimen for HER2-positive disease, with the following footnote: For adult patients with advanced unresectable or metastatic HER2-positive breast cancer, including patients with brain metastases, who have received one or more lines of prior HER2-targeted therapy in the metastatic setting. (BINV-Q, 2 of 7)
• Dose/administration and references updated to include newly added regimens. (BINV-Q, 3 of 7; BINV-Q, 4 of 7; BINV-Q, 6 of 7; BINV-Q, 7 of 7)

BINV-R (2 of 3)
• Dose/administration option added for pembrolizumab: 400 mg IV on day 1, every 6 weeks until disease progression or unacceptable toxicity, or up to 24 months.

Updates in Version 3.2020 of the NCCN Guidelines for Breast Cancer from Version 2.2020 include:

BINV-18
• Footnote jjj modified: In women with a local breast recurrence after breast-conserving surgery who had a prior sentinel node biopsy (SNB), a repeat SNB may be technically possible considered although the accuracy of repeat SNB is unproven. The accuracy of repeat SNB is unproven, and On the other hand, the prognostic significance of repeat SNB after mastectomy is unknown and its use is discouraged.

BINV-Q
• Recurrent or stage IV (M1) HER2-positive disease: Neratinib + capecitabine changed from a category 2B to a category 2A, other recommended regimen.

MS-1
• The Discussion section corresponding to the management of recurrent/stage IV disease has been updated.

Updates in Version 2.2020 of the NCCN Guidelines for Breast Cancer from Version 1.2020 include:

BINV-22 and BINV-24
• Fam-trastuzumab deruxtecan-nxki has been added to the systemic therapy options for recurrent or stage IV (M1) HER2-positive disease.
• Footnote xxx has been added: Fam-trastuzumab deruxtecan-nxki is indicated following two or more lines of prior HER2-targeted therapy in the metastatic setting. This agent is contraindicated for patients with pneumonitis or interstitial lung disease (ILD).

BINV-Q
• Fam-trastuzumab deruxtecan-nxki has been added to the other recommended regimens for HER2-positive recurrent or stage IV (M1) disease.
  ▸ Footnote k added: Fam-trastuzumab deruxtecan-nxki is indicated following two or more lines of prior HER2-targeted therapy in the metastatic setting. This agent is contraindicated for patients with pneumonitis or interstitial lung disease (ILD).
• Footnote l modified: Do not substitute trastuzumab and hyaluronidase-oysk for or with ado-trastuzumab emtansine or fam-trastuzumab deruxtecan-nxki. (Also on BINV-P, footnote g)
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**General:**
- Changed "multigene assays" to "gene expression assays" throughout the guidelines.
- The following footnotes have been added/modified on various BINV pages:
  - Footnote y modified: This includes medullary and micropapillary subtypes. According to WHO, carcinoma of no special type (NST) encompasses multiple patterns including medullary pattern, cancers with neuroendocrine expression, and other rare patterns.
  - Footnote z added: There are rare subtypes of metaplastic carcinoma (eg, low-grade adenosquamous and low-grade fibromatosis-like carcinoma) that are considered to have a favorable prognosis without adjuvant systemic therapies.
  - Footnote aa added: To be associated with favorable prognosis, the favorable histologic type should be pure (>90% as classified on the surgical excision, not core biopsy alone), not high grade and HER2 negative. If non-typical pathologic or clinical features are present, consider treating as ductal/NST (see BINV-4).
  - Footnote bb added: Correlation of histology, hormone receptor, and HER2 status should always be done with awareness of unusual/discordant or borderline results. See Principles of Biomarker Testing (BINV-A).
  - Footnote cc modified: The expression of ER and PR in breast cancer can range from low (1%–10%) to high levels. The biologic behavior of ER/PR-low-expressing tumors may be more similar to ER/PR-negative cancers and this should be considered in decision-making for adjuvant therapy. Although patients with cancers with 1%–100% ER IHC staining are considered ER-positive and eligible for endocrine therapies, there are more limited data on the subgroup of cancers with ER-low–positive (1%–10%) results. The ER-low–positive group is heterogeneous with reported biologic behavior often similar to ER-negative cancers. This should be considered in decision-making for other adjuvant therapy and overall treatment pathway. See Principles of Biomarker Testing (BINV-A).

**DCIS-2**
- Removed links to NCCN Guidelines for Breast Risk Reduction from algorithm and footnote.

**BINV-1**
- Top pathway:
  - Clarified that this pathway is for those not considering preoperative systemic therapy.
  - Moved axillary assessment with exam to BINV-11.
  - Footnote k modified: Breast MRI may be useful for characterizing axillary and/or internal mammary nodal disease. See Principles of Dedicated Breast MRI Testing (BINV-B).
  - Added link to PREG-1 for patients pregnant at time of workup.
  - Revised criteria for consideration of preoperative systemic therapy to ≥T2 or ≥N1, and added a link to BINV-M for more information.
  - Footnote removed: See Principles of Preoperative Systemic Therapy (BINV-M) and See Workup (BINV-11).
  - Added a link to IBC-1 for those diagnosed with inflammatory breast cancer.

**BINV-2**
- Removed criteria for preoperative systemic therapy and link to BINV-11.
- Footnote s added: Consider tangents/high tangents for patients who meet ACOSOG Z0011 criteria.

**BINV-3**
- Footnote w added: In the case of a micrometastasis (>0.2 to ≤2.0 mm), and no axillary dissection, evaluate other patient risk factors when considering RT.

**BINV-4**
- Histologies modified/clarified. (Also on subsequent pages)

**BINV-5**
- Footnote removed: Mixed lobular and ductal carcinoma should be graded based on the ductal component and treated based on this grading. For metaplastic carcinoma, the prognostic value of the histologic grading is uncertain. However, when a specific histologic subtype of metaplastic carcinoma is present and accounts for more than 10% of the tumor, the subtype is an independent prognostic variable.

**Continued**
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-6**
- Footnote kk modified: Other prognostic multigene gene expression assays may be considered to help assess risk of recurrence but have not been validated to predict response to chemotherapy. See...
- Footnote ll modified: Patients with T1b tumors with low-grade histology and no lymphovascular invasion should be treated with endocrine monotherapy as the TAILORx trial did not include patients with such tumors.
- Footnote mm modified: Consider the use of adjuvant chemotherapy in women 50 years of age or younger with a recurrence score of 16–25, based on an exploratory analysis from the TAILORx study demonstrated a potential benefit to chemotherapy in younger patients. See Discussion. Lower-distant recurrences in women 50 years of age or younger randomized to chemotherapy.

**BINV-7**
- Footnote ss added: In select patients with high-risk features (eg, very young women with high-grade histology), adjuvant chemotherapy may be considered (category 2B). See (BINV-L).

**BINV-10**
- Bottom pathway modified. For ER-negative and PR-negative, HER2 negative disease the following recommendation has been added: Limited available data support local therapy only with consideration for systemic/targeted therapies only in node-positive disease.
- Footnote tt added: Encapsulated papillary carcinoma (EPC) without associated conventional invasion is staged as pTis because behavior is similar to DCIS (per AJCC). Solid papillary carcinoma (SPC) should be specified as in situ or invasive based on WHO criteria but both forms have favorable outcomes.

**BINV-11**
- Modified clinical stage: ≥T2,M0 or ≥N1,M0.
- Workup:
  - Added axillary assessment with exam, including consider ultrasound, and percutaneous biopsy of suspicious nodes.
  - Added link to PREG-1 for pregnant patients.
  - Moved breast MRI (optional) under "additional studies consider."
- Following workup, changed "for potentially operable breast cancer" to "for operable breast cancers..."
- Footnote vv modified: At the time of axillary node sampling, a clip or tattoo should be placed to permit verification that the biopsy-positive lymph node has been removed at the time of definitive surgery.

**BINV-12**
- This page has been significantly modified. Recommendations regarding axillary lymph node evaluation/biopsy have been moved to BINV-D.
- Footnote ww added: Sentinel node biopsy can be considered prior to preoperative systemic therapy if the determination of nodal status will influence surgical and/or systemic therapy choices.

**BINV-13**
- Title modified: Potentially Operable Disease: Preoperative Systemic Therapy and Surgical Treatment and Adjuvant Therapy After Preoperative Systemic Treatment
- Added adjuvant therapy options with link to BINV-15 for additional information on adjuvant systemic therapy options.
- Footnote xx modified: The accurate assessment of in-breast tumor or regional lymph node response to preoperative systemic therapy is difficult, and should include physical examination and performance of imaging studies (mammogram and/or breast ultrasound and/or breast MRI) that were abnormal...
- Footnote yy added: Complete planned chemotherapy regimen course if not completed preoperatively. (Also on BINV-14)
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-14**
- Title modified: Inoperable or Locally Advanced Disease (Non-Inflammatory): Preoperative Systemic Therapy and Subsequent Treatment
- Top pathway: Added adjuvant therapy options with link to BINV-15 for additional information on adjuvant systemic therapy options.

**BINV-15**
- Page significantly modified to include adjuvant systemic therapy options based on response to preoperative treatment. This page applies to adjuvant systemic therapy after preoperative systemic therapy for both operable and inoperable disease. (Former pages BINV-14 and BINV-16 have been replaced with this new algorithm.)
- Footnote ccc added: If HER2-targeted therapy and/or endocrine therapy is indicated, it may be administered concurrently with radiation. If indicated, capecitabine should follow completion of RT.

**BINV-16**
- Line added to footnote eee: There are case reports of spontaneous fractures after denosumab discontinuation.

**BINV-17**
- Workup, bullet added: For biomarker testing to identify candidates for additional targeted therapies, see Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease.
- Removed bullet: For patients with HER2-negative tumors under consideration for chemotherapy, strongly consider germline BRCA1/2 testing.
- Modified and moved the following bullets to BINV-R:
  - For HR-positive/HER2-negative breast cancer, assess for PIK3CA mutations with tumor or liquid biopsy identify candidates for alpelisib plus fulvestrant.
  - For triple-negative breast cancer (TNBC), assess PD-L1 expression biomarker status on tumor-infiltrating immune cells to identify patients most likely to benefit from candidates for atezolizumab plus albumin-bound paclitaxel.
- Footnote moved to BINV-R: PIK3CA mutation testing can be done on tumor tissue or ctDNA in peripheral blood (liquid biopsy). If liquid biopsy is negative, tumor tissue testing is recommended.
- Footnote jjj added: For the treatment of brain metastases, see NCCN Guidelines for Central Nervous System Cancers.

**BINV-19**
- Last line of footnote qqq modified: The optimal schedule for zoledronic acid is every 12 weeks monthly x 12, then quarterly.

**BINV-20**
- No visceral crisis and prior endocrine therapy within 1 y, premenopausal and postmenopausal
  - Changed "different endocrine therapy ± CDK4/6 or mTOR inhibitor" to "systemic therapy"
- No visceral crisis and no prior endocrine therapy within 1 y:
  - Premenopausal, modified first option: Ovarian ablation or suppression plus endocrine therapy ± CDK4/6 inhibitor III + systemic therapy
  - Postmenopausal, replaced options with: Systemic therapy
- Footnote uuu added: If progression on initial endocrine therapy, switch to a different endocrine therapy option.
- Footnote removed, addressed on BINV-P: Fulvestrant has been combined with CDK4/6 inhibitors (palbociclib, ribociclib) in the first-line setting in two randomized trials.

**BINV-21**
- Progression or unacceptable toxicity, modified first option: If not endocrine therapy refractory, consider additional line of endocrine therapy ± targeted therapy (see second-line therapy options on BINV-P).
- Modified footnote www: If there is disease progression while on CDK4/6 inhibitor therapy, there are no limited data to support an additional line of therapy...
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-25**
• Footnote ffff added: For triple-negative breast cancer (TNBC), assess PD-L1 expression on tumor-infiltrating immune cells to identify candidates for atezolizumab plus albumin-bound paclitaxel. Assess germline BRCA1/2 mutations to identify candidates for PARP-inhibitor monotherapy. See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R).

**BINV-A (2 of 2)**
• New page added on Principles of Biomarker Testing Hormone Receptor Testing.

**BINV-C**
• Fourth bullet modified: Patients should not become pregnant during treatment with RT, chemotherapy, endocrine therapy, or during or within 6 months of completing trastuzumab or pertuzumab.
• Eighth bullet modified: Breastfeeding is not recommended during active treatment with chemotherapy and endocrine therapy or within 6 months of completing trastuzumab or pertuzumab.

**BINV-D**
• This page has been significantly revised to include axillary staging recommendations for patients who have received preoperative chemotherapy.

**BINV-E**
• Last paragraph added: Lymphedema is a potential side effect after the treatment of axillary lymph node surgery resulting from damage to the lymphatic system. Early detection/diagnosis of lymphedema is key for optimal management. Consider pretreatment measurement of both arms as a baseline for patients with risk factors for lymphedema. See NCCN Guidelines for Survivorship: Lymphedema (SLYMPH-1).

**BINV-I**
• Optimizing delivery of individual therapy:
  ‣ Fourth sub-bullet modified: ... prone positioning may be used to try to further reduce dose to adjacent normal tissues, in particular heart and lung and adjacent normal tissue.
  ‣ Sixth sub-bullet modified: In certain circumstances When using certain techniques (ie, prone breast), more frequent imaging may be appropriate. Routine use of daily imaging is not recommended.

• Regional Nodal Radiation
  ‣ Second sub-bullet modified: Based on the post-mastectomy radiation randomized studies and recent trials, RT of the internal mammary lymph nodes nodal chain to include the first 3 intercostal spaces should be strongly considered when delivering regional nodal irradiation. CT treatment planning should be utilized When treating the internal mammary-lymph nodal volume to evaluate dose to nodes, dose-volume histograms (DVHs) should be used to evaluate dose constraints, dose to normal tissues (heart, lung), and planned target volumes (PTVs). normal tissues, especially the heart and lung, and dose constraints respected.

• Accelerated Partial Breast Irradiation
  ‣ First bullet modified: Preliminary Studies of APBI suggest that rates of local control in selected low-risk patients with early-stage breast cancer may be comparable to those treated with standard WBRT. However, compared to standard whole breast radiation, several recent studies document...

• Preoperative Systemic Therapy
  ‣ Bullet modified: In patients treated with preoperative systemic therapy, adjuvant RT is based on the maximal disease stage (ie, clinical stage, pathologic stage, tumor characteristics) at diagnosis (before preoperative systemic therapy) and pathology results after preoperative systemic therapy.
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-J (1 of 2)**
- First bullet modified: *Few men have been included in breast cancer trials.* clinical trials have specifically focused on male breast cancer.
- Second bullet modified: *Although there are some biologic and clinical differences between breast cancer in men and women, Overall, management of breast cancer in men is similar overall to management...*
  - Second sub-bullet modified: Breast surgery: *Historically, men with breast cancer have undergone mastectomy more often than BCS. However, breast-conserving therapy is increasingly being performed in men and evolving data indicate that breast conservation in men is associated with equivalent outcomes to mastectomy and that it is safe and feasible. Decisions about breast conservation versus mastectomy in men should be made according to similar criteria as for women. While partial mastectomy can be performed in selected cases of male breast cancer, it generally has been reserved for older men with significant comorbid disease or in cases where the male patient is hoping to achieve nipple preservation and is willing to undergo radiation treatment as would be indicated in women with similar disease.*
  - Last sub-bullet modified: Systemic therapy for advanced disease: Management of advanced breast cancer in men is similar to that in women; however, it is preferred that when an aromatase inhibitor is used, a GnRH analog should be given concurrently. Available data suggest single-agent fulvestrant has similar efficacy in men as in women. Newer agents such as CDK4/6 inhibitors in combination with an aromatase inhibitor or fulvestrant, mTOR inhibitors, and PIK3CA inhibitors have not been systematically evaluated in clinical trials in men with breast cancer. However, available real-world data suggest comparable efficacy and safety profiles and it is reasonable to recommend these agents to men based on extrapolation of data from studies comprised largely of female participants with advanced breast cancer. Newer agents such as CDK4/6 inhibitors and mTOR inhibitors have not been evaluated in men, but it is reasonable to recommend them in men based on data from studies of women with advanced breast cancer.

**BINV-J (2 of 2)**
- References have been updated.

**BINV-K**
- Following adjuvant therapy with an aromatase inhibitor for 5 y, the recommended duration to continue an aromatase inhibitor has been modified from an additional 5 y to an additional 3-5 y for patients that were postmenopausal at diagnosis.
- Footnote a added: If patient is not postmenopausal, sequential evaluation of hormonal status is recommended to consider an alternative endocrine agent.

**BINV-L**
- Other recommended preoperative therapy regimens added for select patients with triple-negative breast cancer:
  - Weekly paclitaxel + carboplatin
  - Docetaxel + carboplatin
- Footnote j added: The inclusion of platinum agents as neoadjuvant chemotherapy for triple-negative breast cancer remains controversial. Several studies have shown improved pCR rates with incorporation of platinum. However, long-term outcomes remain unknown. The routine use of platinum agents as part of neoadjuvant therapy for triple-negative breast cancer is not recommended for most patients (including BRCA mutation carriers), but it may be considered in select patients (such as those for whom achieving better local control is necessary). The use of platinum agents in the adjuvant setting is not recommended. If platinum agents are included in an anthracycline based regimen, the optimal sequence of chemotherapy and choice of taxane agent is not established.

**BINV-L (3 of 6)**
- Dosing information updated with regimens added.

**BINV-L (6 of 6)**
- References updated.

Continued
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-M (1 of 2)**
- Moved benefits and criteria for preoperative systemic therapy from page 2 to page 1.
- Candidates for Preoperative Systemic Therapy,
  - Modified second bullet: Patients with operable breast cancer, *preoperative systemic therapy is preferred for those with:*
  - Added: HER2-positive disease and triple-negative breast cancer, if \( T \geq 2 \) or \( N \geq 1 \).
  - Added: If time needed to decide surgical options.

**BINV-M (2 of 2)**
- Sixth bullet modified: Patients with HER2-positive tumors should be treated with preoperative systemic therapy incorporating trastuzumab for at least 9 weeks of preoperative therapy.
- Eighth bullet modified: Tumor response should be routinely assessed by clinical exam *and imaging studies (see footnote tt on BINV-13) during delivery of preoperative therapy.

**BINV-N**
- Table reformatted.

**BINV-N (3 of 4)**
- Added to 12-gene treatment implications: The risk score is predictive of chemo-benefit based on a prospective analysis of 3,746 archived, HR-positive, HER2-negative, T1–T3 tumors from chemo-endocrine and endocrine-only cohorts, that included women with lymph node-negative and lymph node-positive disease.
- Added to Breast Cancer Index treatment implications: Results of a secondary analysis of the aTTom trial demonstrated that in patients with hormone-receptor positive, node-positive breast cancer, patients with a high BCI (HOXB13/IL17BR) (H/I) derived significant benefit from extending tamoxifen therapy to 10 years versus 5 years. In contrast, BCI (H/I) low pts derived no benefit from extended adjuvant therapy.

**BINV-N (4 of 4)**
- References updated.

**BINV-P**
- HER2-Negative and Postmenopausal or Premenopausal Receiving Ovarian Ablation or Suppression:
  - Separated preferred regimens for first-line therapy from preferred regimens for second- and subsequent-line therapy.
  - Preferred first-line option added: Selective ER down-regulator (fulvestrant, category 1) ± *non-steroidal aromatase inhibitor (anastrozole, letrozole) (category 1)*
  - Useful in certain circumstances, option removed: ribociclib + tamoxifen (category 1)
  - Footnote removed: CDK4/6 inhibitor (abemaciclib, palbociclib, or ribociclib) in combination with an aromatase inhibitor (anastrozole, letrozole, or exemestane) or fulvestrant may be considered as a treatment option for first-line therapy for women who are postmenopausal or premenopausal (receiving ovarian suppression or ablation with an LHRH agonist) with hormone-receptor positive, HER2-negative metastatic breast cancer. Fulvestrant has been combined with CDK4/6 inhibitors (ie, palbociclib, ribociclib) in the first-line setting in two randomized trials.
  - Footnote b modified: ...addition of fulvestrant to anastrozole resulted in prolongation of time to progression and overall survival.
  - Footnote added: See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R).
  - Footnote removed: Ribociclib + tamoxifen is not considered a preferred first-line therapy due to QTc prolongation risk but may be considered in certain circumstances as a treatment option for first-line therapy with ovarian suppression or ablation for premenopausal patients with hormone-receptor positive, HER2-negative metastatic breast cancer.

Continued
Updates in Version 1.2020 of the NCCN Guidelines for Breast Cancer from Version 3.2019 include:

**BINV-Q (1 of 7)**
- HER2-Negative
  - Moved targeted therapy options to BINV-R and linked to that page in the table of options.
  - Added regimen under useful in certain circumstances: Carboplatin + paclitaxel or albumin-bound paclitaxel
- HER2-Positive Disease, other recommended regimen added: Neratinib + capcitabine (category 2B)
- Footnote removed: Patients with TNBC, assess PD-L1 biomarker status on tumor-infiltrating immune cells to identify patients most likely to benefit from atezolizumab plus albumin-bound paclitaxel.
- Footnotes added:
  - See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R)
  - For treatment of brain metastases, see NCCN Guidelines for Central Nervous System Cancers.

**BINV-Q (3 of 7)**
- Dosing information added for new regimens.
- Dosing for targeted therapies moved to BINV-R.

**BINV-Q (5 of 7)**
- Vinorelbine dosing modified for trastuzumab + vinorelbine regimen.
- Dosing added for new regimens.

**BINV-Q (6 of 7)**
- References updated.

**BINV-R**
- New section added, titled "Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease."
- The following FDA approved agents have been added as useful in certain circumstances options:
  - Larotrectinib (category 2A)
  - Entrectinib (category 2A)
  - Pembrolizumab (category 2A)

**BINV-S**
- Components of monitoring, added: Clinicians should take into account patient preferences through a shared decision-making process.

**PHYLL-1**
- Following wide excision without axillary staging, added "clinical follow-up for 3 y."
- Footnote c modified: For malignant or borderline disease, wide excision means excision with the intention...

**PREG-1**
- Added workup.
- Added footnote a: CT scans and nuclear imaging are contraindicated during pregnancy.
- Modified footnote: ...Chemotherapy should not be administered during the first trimester of pregnancy, and RT should not be administered during any trimester of pregnancy. Coordination is recommended between the oncology and obstetrics teams to plan the optimal timing of systemic therapy administration during pregnancy. Most experience...

**IBC-1**
- Workup
  - Modified first bullet: History and physical exam by multidisciplinary team and obtain medical photography
  - Removed bullet: Chest diagnostic CT with contrast (if pulmonary symptoms are present)
Ductal Carcinoma in Situ (DCIS)

DIAGNOSIS

DCIS
Tis,N0,M0

WORKUP

- History and physical exam
- Diagnostic bilateral mammogram
- Pathology review
- Determination of tumor estrogen receptor (ER) status
- Genetic counseling if patient is at risk for hereditary breast cancer
- Breast MRI as indicated

PRIMARY TREATMENT

Lumpectomy without lymph node surgery + whole breast radiation therapy (WBRT) (category 1) with or without boost to tumor bed or Total mastectomy with or without sentinel node biopsy + reconstruction (optional)
or Lumpectomy without lymph node surgery + accelerated partial breast irradiation (APBI) or Lumpectomy without lymph node surgery without radiation therapy (RT) (category 2B)

See Postsurgical Treatment (DCIS-2)

See Principles of Radiation Therapy (BINV-I).

Patients found to have invasive disease at total mastectomy or re-excision should be managed as having clinical stage I or stage II disease (See ST-1), including lymph node staging.

See Special Considerations to Breast-Conserving Therapy Requiring Radiation Therapy (BINV-G).

WBRT following lumpectomy reduces recurrence rates in DCIS by about 50%. Approximately half of the recurrences are invasive and half are DCIS. A number of factors determine local recurrence risk: palpable mass, larger size, higher grade, close or involved margins, and age <50 years. If the patient and physician view the individual risk as “low,” some patients may be treated by excision alone. Select patients with low-risk DCIS may be considered suitable for APBI if they meet all aspects of the definition of low-risk DCIS from the RTOG 9804 trial, including screen-detected DCIS, low to intermediate nuclear grade, tumor size ≤2.5 cm, and surgical resection with margins negative at >3 mm.

See Principles of Breast Reconstruction Following Surgery (BINV-H).

b For risk criteria, See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.
c See Principles of Dedicated Breast MRI Testing (BINV-B).
d The use of MRI has not been shown to increase likelihood of negative margins or decrease conversion to mastectomy. Data to support improved long-term outcomes are lacking.
e Re-resection(s) may be performed in an effort to obtain negative margins in patients desiring breast-conserving therapy. Patients in whom adequate surgical margins cannot be achieved with lumpectomy should undergo a total mastectomy. For definition of adequate surgical margins, see Margin Status Recommendations for DCIS and Invasive Breast Cancer (BINV-F).
f Complete axillary lymph node dissection should not be performed in the absence of evidence of invasive cancer or proven axillary metastatic disease in women with apparent pure DCIS. However, a small proportion of patients with apparent pure DCIS will be found to have invasive cancer at the time of their definitive surgical procedure. Therefore, the performance of a sentinel lymph node procedure should be strongly considered if the patient with apparent pure DCIS is to be treated with mastectomy or with excision in an anatomic location compromising the performance of a future sentinel lymph node procedure.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Risk reduction therapy for ipsilateral breast following breast-conserving surgery (BCS):
- Consider endocrine therapy for 5 years for:
  - Patients treated with breast-conserving therapy (lumpectomy) and RT\textsuperscript{m} (category 1), especially for those with ER-positive DCIS.
  - The benefit of endocrine therapy for ER-negative DCIS is uncertain
- Patients treated with excision alone\textsuperscript{l}
- Endocrine therapy:
  - Tamoxifen\textsuperscript{m} for premenopausal patients
  - Tamoxifen\textsuperscript{m} or aromatase inhibitor for postmenopausal patients with some advantage for aromatase inhibitor therapy in patients <60 years or with concerns for thromboembolism

Risk reduction therapy for contralateral breast:
- Counseling regarding risk reduction

\textsuperscript{l} Available data suggest endocrine therapy provides risk reduction in the ipsilateral breast treated with breast conservation and in the contralateral breast in patients with mastectomy or breast conservation with ER-positive primary tumors. Since a survival advantage has not been demonstrated, individual consideration of risks and benefits is important.

\textsuperscript{m} CYP2D6 genotype testing is not recommended in women who are considering tamoxifen.
**CLINICAL STAGE**

**WORKUP**

- History and physical exam
- Imaging:
  - Diagnostic bilateral mammogram
  - Ultrasound as necessary
  - Breast MRI (optional), with special consideration for mammographically occult tumors
- Pathology review
- Determination of tumor estrogen/progesterone receptor (ER/PR) status and HER2 status
- Genetic counseling if patient is at risk for hereditary breast cancer
- Counseling for fertility concerns if premenopausal
- Pregnancy test in all women of childbearing potential (If pregnant, see PREG-1)
- Assess for distress

Consider additional studies only if directed by signs or symptoms of metastatic disease:
- Complete blood count (CBC)
- Comprehensive metabolic panel, including liver function tests and alkaline phosphatase
- Bone scan indicated if localized bone pain or elevated alkaline phosphatase or sodium fluoride PET/CT (category 2B)
- Abdominal ± pelvic diagnostic CT with contrast or MRI with contrast indicated if elevated alkaline phosphatase, abnormal liver function tests, abdominal symptoms, or abnormal physical examination of the abdomen or pelvis
- Chest diagnostic CT with contrast (if pulmonary symptoms present)
- FDG PET/CT (optional)

See Locoregional Treatment (BINV-2)

If considering preoperative systemic therapy for ≥T2 or ≥N1 (Candidates for preoperative systemic therapy, see BINV-M)

See Workup Prior to Preoperative Systemic Therapy (BINV-11)

Recurrent or Stage IV (M1)

See Workup for Recurrent or Stage IV (M1) Disease (BINV-17)

Clinical pathologic diagnosis of inflammatory breast cancer (IBC)

See Inflammatory Breast Cancer (IBC-1)

---

For tools to aid optimal assessment and management of older adults, see NCCN Guidelines for Older Adult Oncology.

Breast MRI may be useful for characterizing axillary and/or internal mammary nodal disease. See Principles of Dedicated Breast MRI Testing (BINV-B).

For risk criteria, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic.

See Fertility and Birth Control (BINV-C).

See NCCN Guidelines for Distress Management.

Routine systemic staging is not indicated for early breast cancer in the absence of symptoms.

Bone scan or sodium fluoride PET/CT may not be needed if FDG PET/CT is performed and clearly indicates bone metastasis, on both the PET and CT component.

FDG PET/CT can be performed at the same time as diagnostic CT. The use of PET or PET/CT is not indicated in the staging of clinical stage I, II, or operable stage III breast cancer. FDG PET/CT is most helpful in situations where standard staging studies are equivocal or suspicious, especially in the setting of locally advanced or metastatic disease.

FDG PET/CT may also be helpful in identifying unsuspected regional nodal disease and/or distant metastases in locally advanced breast cancer when used in addition to standard staging studies.

---

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
LOCOREGIONAL TREATMENT OF T1–3,N0–1,M0 DISEASE

Lumpectomy with surgical axillary staging (category 1)\(^{l,m,n}\)

- ≥4 positive\(^q\) axillary nodes
  - Whole breast radiation therapy (WBRT) with or without boost\(^r\) to tumor bed (category 1), infraclavicular region, supraclavicular area, internal mammary nodes, and any part of the axillary bed at risk (category 1). It is common for RT to follow chemotherapy when chemotherapy is indicated.

- 1–3 positive axillary nodes
  - WBRT with or without boost\(^r\) to tumor bed (category 1). Strongly consider RT to infracavicular region, supraclavicular area, internal mammary nodes, and any part of the axillary bed at risk.\(^s\) It is common for RT to follow chemotherapy when chemotherapy is indicated.

- Negative axillary nodes
  - WBRT with or without boost\(^r\) to tumor bed, and consider regional nodal irradiation with exclusion of the dissected portion of the axilla in patients with central/medial tumors or tumors >2 cm with other high-risk features (young age or extensive lymphovascular invasion [LVI]).
  - Consideration of APBI in selected low-risk patients.\(^r,t\)
  - It is common for RT to follow chemotherapy when chemotherapy is indicated.\(^u\)

Total mastectomy with surgical axillary staging\(^{l,m,o}\) (category 1) ± reconstruction\(^p\) → See Locoregional Treatment (BINV-3)

\(^{a}\) For tools to aid optimal assessment and management of older adults, see NCCN Guidelines for Older Adult Oncology.

\(^{l}\) See Surgical Axillary Staging (BINV-D).

\(^{m}\) See Axillary Lymph Node Staging (BINV-E) and Margin Status Recommendations for DCIS and Invasive Disease (BINV-F).

\(^{n}\) See Special Considerations to Breast-Conserving Therapy Requiring Radiation Therapy (BINV-G).

\(^{o}\) Except as outlined in the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic and the NCCN Guidelines for Breast Cancer Risk Reduction, prophylactic mastectomy of a breast contralateral to a known unilateral breast cancer is discouraged. When considered, the small benefits from contralateral prophylactic mastectomy for women with unilateral breast cancer must be balanced with the risk of recurrent disease from the known ipsilateral breast cancer, psychological and social issues of bilateral mastectomy, and the risks of contralateral mastectomy. The use of a prophylactic mastectomy contralateral to a breast treated with breast-conserving therapy is very strongly discouraged.

\(^{p}\) See Principles of Breast Reconstruction Following Surgery (BINV-H).

\(^{q}\) Consider imaging for systemic staging, including chest/abdominal ± pelvic diagnostic CT with contrast, bone scan, and optional FDG PET/CT (See BINV-1).

\(^{r}\) See Principles of Radiation Therapy (BINV-I).

\(^{s}\) Consider tangents/high tangents for patients who meet ACOSOG Z0011 criteria.

\(^{t}\) PBI may be administered prior to chemotherapy.

\(^{u}\) Breast irradiation may be omitted in patients ≥70 y of age with ER-positive, clinically node-negative, T1 tumors who receive adjuvant endocrine therapy (category 1).
LOCOREGIONAL TREATMENT OF T1–3,N0–1,M0 DISEASEa,v

Total mastectomy with surgical axillary staging1,m (category 1) ± reconstructionp

- ≥4 positive axillary nodesq
- 1–3 positive axillary nodesw
- Negative axillary nodes and tumor >5 cm
- Margins positive
- Negative axillary nodes and tumor ≤5 cm and negative margins but <1 mm
- Negative axillary nodes and tumor ≤5 cm and margins ≥1 mm

RTt to chest wall + infraclavicular region, supraclavicular area, internal mammary nodes, and any part of the axillary bed at risk (category 1). It is common for RT to follow chemotherapy when chemotherapy is indicated.

Strongly consider RTt to chest wall + supraclavicular area, internal mammary nodes, and any part of the axillary bed at risk. It is common for RT to follow chemotherapy when chemotherapy is indicated.

Consider RTt to chest wall ± infraclavicular region, ± supraclavicular area, ± internal mammary nodes and any part of the axillary bed at risk. It is common for RT to follow chemotherapy when chemotherapy is indicated.

Re-excision to negative margins is preferred. If not feasible, then strongly consider RTt to chest wall ± infraclavicular region, ± supraclavicular area, ± internal mammary nodes and any part of the axillary bed at risk. It is common for RT to follow chemotherapy when chemotherapy is indicated.

Consider RTt to chest wall, ± regional nodal radiation in patients with central/medial tumors or tumors >2 cm with other high-risk features (young age or extensive LVI). It is common for RT to follow chemotherapy when chemotherapy is indicated.

No RTx

See BINV-4

a For tools to aid optimal assessment and management of older adults, see NCCN Guidelines for Older Adult Oncology.
1 See Surgical Axillary Staging (BINV-D).
m See Axillary Lymph Node Staging (BINV-E) and See Margin Status Recommendations for DCIS and Invasive Disease (BINV-F).
q Consider imaging for systemic staging, including chest/abdominal ± pelvic diagnostic CT with contrast, bone scan, and optional FDG PET/CT (See BINV-1).
rt See Principles of Radiation Therapy (BINV-I).
v See Special Consideration for Breast Cancer in Men (BINV-J).
w In the case of a micrometastasis (>0.2 to ≤2.0 mm), and no axillary dissection, evaluate other patient risk factors when considering RT.
x Postmastectomy RT may be considered for patients with multiple high-risk recurrence factors, including central/medial tumors or tumors >2 cm with other high-risk features such as young age and/or extensive LVI.
According to WHO, carcinoma of no special type (NST) encompasses multiple patterns including medullary pattern, cancers with neuroendocrine expression, and other rare patterns.

There are rare subtypes of metaplastic carcinoma (e.g., low-grade adenosquamous and low-grade fibromatosis-like carcinoma) that are considered to have a favorable prognosis without adjuvant systemic therapies.

To be associated with a favorable prognosis, the favorable histologic type should be pure (>90% as classified on the surgical excision, not core biopsy alone), not high grade and HER2 negative. If non-typical pathologic or clinical features are present, consider treating as ductal/NST.

### Systemic Adjuvant Treatment

#### HER2-positive and/or PR-positive

- **HER2-negative**

#### Favorable histologic type:

- Pure tubular
- Pure mucinous
- Pure cribriform
- Encapsulated or solid papillary carcinoma
- Other rare forms

### Herceptin Pathway

#### Correlation of histology, hormone receptor, and HER2 status should always be done with awareness of unusual/discordant or borderline results.

**See Principles of Biomarker Testing (BINV-A).**

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
SYSTEMIC ADJUVANT TREATMENT: HORMONE RECEPTOR-POSITIVE - HER2-POSITIVE DISEASE

- Ductal/NST
- Lobular
- Mixed
- Micropapillary

Node positive (1 or more ipsilateral metastases >2 mm)

pT1, pT2, or pT3; and pN0 or pN1mi (≤2 mm axillary node metastasis)

Tumor ≤0.5 cm

pN0

Tumor 0.6–1.0 cm

pN1mi

Tumor >1 cm

Consider adjuvant endocrine therapy\textsuperscript{dd,ee} ± adjuvant chemotherapy\textsuperscript{ff,gg} with trastuzumab\textsuperscript{hh,ii} (category 2B)

Adjuvant chemotherapy\textsuperscript{ff,gg} with trastuzumab (category 1) and endocrine therapy\textsuperscript{dd,ee}

Adjuvant chemotherapy\textsuperscript{ff,gg} with trastuzumab\textsuperscript{hh} and endocrine therapy\textsuperscript{dd,ee}

Adjuvant chemotherapy\textsuperscript{ff,gg} with trastuzumab\textsuperscript{hh} (category 1) and endocrine therapy\textsuperscript{dd,ee,ji} or

Adjuvant chemotherapy\textsuperscript{ff,gg} with trastuzumab\textsuperscript{hh} + pertuzumab and endocrine therapy\textsuperscript{dd,ee,jj}

\textsuperscript{d} See Principles of Biomarker Testing (BINV-A).
\textsuperscript{v} See Special Considerations for Breast Cancer in Men (BINV-J).
\textsuperscript{y} According to WHO, carcinoma of NST encompasses multiple patterns including medullary pattern, cancers with neuroendocrine expression, and other rare patterns. Although patients with cancers with 1%–100% ER IHC staining are considered ER-positive and eligible for endocrine therapies, there are more limited data on the subgroup of cancers with ER-low–positive (1%–10%) results. The ER-low–positive group is heterogeneous with reported biologic behavior often similar to ER-negative cancers. This should be considered in decision-making for other adjuvant therapy and overall treatment pathway. See Principles of Biomarker Testing (BINV-A).

\textsuperscript{dd} Consider adjuvant bisphosphonate therapy in postmenopausal (natural or induced) patients receiving adjuvant therapy.

\textsuperscript{ee} Evidence supports that the magnitude of benefit from surgical or radiation ovarian ablation in premenopausal women with hormone receptor-positive breast cancer is similar to that achieved with CMF alone. See Adjuvant Endocrine Therapy (BINV-K).

\textsuperscript{ff} Chemotherapy and endocrine therapy used as adjuvant therapy should be given sequentially with endocrine therapy following chemotherapy. Available data suggest that sequential or concurrent endocrine therapy with RT is acceptable. See Adjuvant Endocrine Therapy (BINV-K) and Preoperative/Adjuvant Therapy Regimens (BINV-L).

\textsuperscript{gg} There are limited data to make chemotherapy recommendations for those >70 y of age. See NCCN Clinical Practice Guidelines for Older Adult Oncology.

\textsuperscript{hh} The prognosis of patients with T1a and T1b tumors that are node negative is uncertain even when HER2 is amplified or overexpressed. This is a population of breast cancer patients that was not studied in the available randomized trials. The decision for use of trastuzumab therapy in this cohort of patients must balance the known toxicities of trastuzumab, such as cardiac toxicity, and the uncertain, absolute benefits that may exist with trastuzumab therapy.

\textsuperscript{ii} Adjuvant chemotherapy with weekly paclitaxel and trastuzumab (Tolaney et al. NEJM 2015) can be considered for T1,N0,M0, HER2-positive cancers, particularly if the primary cancer is hormone receptor-negative. The absolute benefit of HER2-based systemic chemotherapy is likely negligible in patients with hormone receptor-positive cancers and tumor size bordering on T1mic (<1 mm), when the estimated recurrence risk is less than 5% and endocrine therapy remains a viable option for systemic treatment.

\textsuperscript{jj} Consider extended adjuvant neratinib following adjuvant trastuzumab-containing therapy for patients with HR-positive, HER2-positive disease with a perceived high risk of recurrence. The benefit or toxicities associated with extended neratinib in patients who have received pertuzumab is unknown.
**SYSTEMIC ADJUVANT TREATMENT: NODE-NEGATIVE - HORMONE RECEPTOR-POSITIVE - HER2-NEGATIVE DISEASE**

- **Tumor ≤0.5 cm**
  - pT1, pT2, or pT3; and pN0
  - **Consider adjuvant endocrine therapy** (category 2B)
    - Adjuvant endocrine therapy or
    - Adjuvant chemotherapy followed by endocrine therapy (category 1)

- **Tumor >0.5 cm**
  - Strongly consider 21-gene RT-PCR assay (category 1)
  - Not done
    - Recurrence score <26
      - Adjuvant endocrine therapy or
      - Adjuvant chemotherapy followed by endocrine therapy (category 1)
    - Recurrence score 26–30
      - Adjuvant endocrine therapy or
      - Adjuvant chemotherapy followed by endocrine therapy (category 1)
    - Recurrence score ≥31
      - Adjuvant chemotherapy followed by endocrine therapy (category 1)
  - See Follow-Up (BINV-16)

---

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Systemic Adjuvant Treatment: Node-Positive - Hormone Receptor-Positive - HER2-Negative Disease

- pN1mi (≤2 mm axillary node metastasis) or N1^{nn} (less than 4 nodes)

- Initial decision-making for adjuvant systemic chemotherapy based on:
  - Clinical characteristics
  - Tumor stage
  - Pathology

- Patient is a candidate for chemotherapy:
  - Consider gene expression assay to assess prognosis^{pp} and determine chemotherapy benefit

- Patient is a candidate for chemotherapy and gene expression assay not available:
  - Use clinical and pathologic features for decision-making

- Adjuvant endocrine therapy^{dd,ee}

- Adjuvant endocrine therapy^{dd,ee} or Adjuvant chemotherapy^{ff,gg} followed by endocrine therapy^{dd,ee} (category 1)

- Adjuvant chemotherapy^{ff,gg} followed by endocrine therapy^{dd,ee} (category 1)

- Node positive (4 or more ipsilateral metastases >2 mm)^oo

- Patient not a candidate for chemotherapy

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

See Principles of Biomarker Testing (BINV-A).

See Special Considerations for Breast Cancer in Men (BINV-J).

Although patients with cancers with 1%–100% ER IHC staining are considered ER-positive and eligible for endocrine therapies, there are more limited data on the subgroup of cancers with ER-low–positive (1%–10%) results. The ER-low–positive group is heterogeneous with reported biologic behavior often similar to ER-negative cancers. This should be considered in decision-making for other adjuvant therapy and overall treatment pathway. See Principles of Biomarker Testing (BINV-A).

Consider adjuvant bisphosphonate therapy in postmenopausal (natural or induced) patients receiving adjuvant therapy.

Evidence supports that the magnitude of benefit from surgical or radiation ovarian ablation in premenopausal women with hormone receptor-positive breast cancer is similar to that achieved with CMF alone. See Adjuvant Endocrine Therapy (BINV-K).

Chemotherapy and endocrine therapy used as adjuvant therapy should be given sequentially with endocrine therapy following chemotherapy. Available data suggest that sequential or concurrent endocrine therapy with RT is acceptable. See Adjuvant Endocrine Therapy (BINV-K) and Preoperative/Adjuvant Therapy Regimens (BINV-L).

There are limited data to make chemotherapy recommendations for those >70 y of age. See NCCN Clinical Practice Guidelines for Older Adult Oncology.

In N1mi and N1, gene expression assays are prognostic and not proven to be predictive of chemotherapy benefit but can be used to identify a low-risk population that when treated with proper endocrine therapy may derive little absolute benefit from chemotherapy. Regarding the 21-gene RT-PCR assay, a secondary analysis of a prospective trial suggests that the test is predictive for women with 1–3 involved ipsilateral axillary lymph nodes. Other gene expression assays have not proven to be predictive of chemotherapy benefit.

There are few data regarding the role of gene expression assays in women with four or more ipsilateral axillary lymph nodes. Decisions to administer adjuvant chemotherapy for this group should be based on clinical factors.

See Gene Expression Assays for Consideration of Addition of Adjuvant Systemic Chemotherapy to Adjuvant Endocrine Therapy (BINV-N).

$^{gg}$ There are limited data to make chemotherapy recommendations for those >70 y of age. See NCCN Clinical Practice Guidelines for Older Adult Oncology.

$^{ss}$ Encapsulated papillary carcinoma (EPC) without associated conventional invasion is staged as pTis because behavior is similar to DCIS (per AJCC). Solid papillary carcinoma (SPC) should be specified as in situ or invasive based on WHO criteria but both forms have favorable outcomes.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
WORKUP PRIOR TO PREOPERATIVE SYSTEMIC THERAPY

**CLINICAL STAGE**

≥T2,M0 or ≥N1,M0

(if considering preoperative systemic therapy)

**WORKUP**

- History and physical exam
- Diagnostic bilateral mammogram; ultrasound as necessary
- Axillary assessment with exam
  - consider ultrasound
  - percutaneous biopsy of suspicious nodes
- Pathology review
- Determination of tumor ER/PR status and HER2 status
- Genetic counseling if patient is at risk for hereditary breast cancer
- Counseling for fertility concerns if premenopausal; pregnancy test in all women of childbearing potential
- Assess for distress

Additional studies consider:

- CBC
- Comprehensive metabolic panel, including liver function tests and alkaline phosphatase
- Chest diagnostic CT with contrast
- Abdominal ± pelvic diagnostic CT with contrast or MRI with contrast
- Bone scan or sodium fluoride PET/CT (category 2B)
- FDG PET/CT (optional)
- Breast MRI (optional), with special consideration for mammographically occult tumors

**For operable breast cancers:** See Breast and Axillary Evaluation Prior to Preoperative Systemic Therapy (BINV-12)

**For inoperable breast cancers:** See Preoperative Systemic Therapy (BINV-14)

---

| a | For tools to aid optimal assessment and management of older adults, see NCCN Guidelines for Older Adult Oncology. |
| b | Breast MRI may be useful for characterizing axillary and/or internal mammary nodal disease. See Principles of Dedicated Breast MRI Testing (BINV-B). |
| d | See Principles of Biomarker Testing (BINV-A). |
| e | For risk criteria, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic. |
| f | See Fertility and Birth Control (BINV-C). |
| g | See NCCN Guidelines for Distress Management. |
| h | Routine systemic staging is not indicated for early breast cancer in the absence of symptoms. |

---

For operable breast cancers: See Breast and Axillary Evaluation Prior to Preoperative Systemic Therapy (BINV-12)

Bone scan or sodium fluoride PET/CT may not be needed if FDG PET/CT is performed and clearly indicates bone metastasis, on both the PET and CT component.

FDG PET/CT can be performed at the same time as diagnostic CT. The use of PET or PET/CT is not indicated in the staging of clinical stage I, II, or operable stage III breast cancer. FDG PET/CT is most helpful in situations where standard staging studies are equivocal or suspicious, especially in the setting of locally advanced or metastatic disease.

FDG PET/CT may also be helpful in identifying unsuspected regional nodal disease and/or distant metastases in locally advanced breast cancer when used in addition to standard staging studies.

At the time of axillary node sampling, a clip or tattoo should be placed to permit verification that the biopsy-positive lymph node has been removed at the time of definitive surgery.

---

Note: All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Prior to preoperative systemic therapy, perform:

- Core biopsy of breast with placement of image-detectable marker(s), if not previously performed, must be done to demarcate the tumor bed for surgical management after preoperative systemic therapy
- Axillary imaging with ultrasound or MRI (if not previously done)
- Biopsy of suspicious and/or clinically positive axillary lymph nodes, if not previously done

See Surgical Treatment and Adjuvant Therapy After Preoperative Systemic Therapy (BINV-13)
### OPERABLE DISEASE: SURGICAL TREATMENT AND ADJUVANT THERAPY AFTER PREOPERATIVE SYSTEMIC TREATMENT

<table>
<thead>
<tr>
<th>RESPONSE&lt;sup&gt;ww&lt;/sup&gt;</th>
<th>SURGICAL TREATMENT</th>
<th>ADJUVANT THERAPY</th>
</tr>
</thead>
</table>
| Complete response orPartial response, lumpectomy possible | Lumpectomy with surgical axillary staging<sup>1</sup> (see BINV-D) | Adjuvant systemic therapy<sup>tt,xx</sup> (see BINV-15) and Post-lumpectomy adjuvant RT<sup>r</sup>  
- Clinical N1 and ypN0: Adjuvant RT to the whole breast with or without boost to the tumor bed; and strongly consider radiation to the supraclavicular/infraclavicular region, area, internal mammary nodes, and any part of the axillary bed at risk  
- Any ypN+: Adjuvant RT to the whole breast (with or without boost to the tumor bed) with inclusion of the supraclavicular/infraclavicular region, area, internal mammary nodes, and any part of the axillary bed |

| Partial response, lumpectomy not possible orConfirmed progressive disease at any time, lumpectomy not possible | Mastectomy and surgical axillary staging<sup>1</sup> (see BINV-D) + reconstruction (optional)<sup>p</sup> | Adjuvant systemic therapy<sup>tt,xx</sup> (see BINV-15) and Post-mastectomy adjuvant RT<sup>r</sup>  
• Clinical N1 and ypN0: Strongly consider RT to the chest wall, supraclavicular/infraclavicular regions, internal mammary nodes, and any part of the axillary bed at risk  
• Any ypN+: RT is indicated to the chest wall + supraclavicular/infraclavicular regions, internal mammary nodes, and any part of the axillary bed at risk |

<sup>1</sup> See Surgical Axillary Staging (BINV-D).  
<sup>p</sup> See Principles of Breast Reconstruction Following Surgery (BINV-H).  
<sup>r</sup> See Principles of Radiation Therapy (BINV-I).  
<sup>tt</sup> See Principles of Preoperative Systemic Therapy (BINV-M).  
<sup>ww</sup> The accurate assessment of in-breast tumor or regional lymph node response to preoperative systemic therapy is difficult, and should include physical examination and performance of imaging studies (mammogram and/or breast ultrasound and/or breast MRI) that were abnormal at the time of initial tumor staging. Selection of imaging methods prior to surgery should be determined by the multidisciplinary team.  
<sup>xx</sup> Complete planned chemotherapy regimen course if not completed preoperatively.

---

**Note:** All recommendations are category 2A unless otherwise indicated.  
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
### INOPERABLE OR LOCALLY ADVANCED DISEASE (NON-INFLAMMATORY):
#### PREOPERATIVE SYSTEMIC THERAPY AND SUBSEQUENT TREATMENT

#### RESPONSE

- **Response to preoperative systemic therapy and tumor is operable**
  - Mastectomy and surgical axillary staging + reconstruction (optional)
  - Lumpectomy with surgical axillary staging
  - Adjuvant systemic therapy (see BINV-15)
  - Adjuvant RT to the whole breast or chest wall, supraclavicular/infraclavicular regions, internal mammary nodes, and any part of the axillary bed at risk

- **No response to preoperative systemic therapy and tumor remains inoperable**
  - Consider additional systemic chemotherapy and/or preoperative radiation
  - Follow pathway above

#### LOCOREGIONAL TREATMENT

- **Individualize treatment**

---

1 See Surgical Axillary Staging (BINV-D).

2 See Principles of Breast Reconstruction Following Surgery (BINV-H).

3 See Principles of Radiation Therapy (BINV-I).

4 See Principles of Preoperative Systemic Therapy (BINV-M).

6 The accurate assessment of in-breast tumor or regional lymph node response to preoperative systemic therapy is difficult, and should include physical examination and performance of imaging studies (mammogram and/or breast ultrasound and/or breast MRI) that were abnormal at the time of initial tumor staging. Selection of imaging methods prior to surgery should be determined by the multidisciplinary team.

xx Complete planned chemotherapy regimen course if not completed preoperatively.

yy For patients with skin and/or chest wall involvement (T4 non-inflammatory) prior to preoperative systemic therapy, breast conservation may be performed in carefully selected patients based on a multidisciplinary assessment of local recurrence risk. In addition to standard contraindications to breast conservation (see BINV-G), exclusion criteria for breast conservation include: inflammatory (T4d) disease before preoperative systemic therapy and incomplete resolution of skin involvement after preoperative systemic therapy.

---

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
### ADJUVANT SYSTEMIC THERAPY AFTER PREOPERATIVE SYSTEMIC THERAPY

<table>

</tr>
<tr>
<td>ypT1–4N0 or residual disease or ypN≥1 or node positive</td>
<td>Consider capecitabine (6–8 cycles) ( \text{zz} )</td>
</tr>
</tbody>
</table>

**ff** Chemotherapy and endocrine therapy used as adjuvant therapy should be given sequentially with endocrine therapy following chemotherapy. Available data suggest that sequential or concurrent endocrine therapy with RT is acceptable. See Adjuvant Endocrine Therapy (BINV-K) and Preoperative/Adjuvant Therapy Regimens (BINV-L).

**zz** If HER2-targeted therapy and/or endocrine therapy is indicated, it may be administered concurrently with radiation. If indicated, capecitabine should follow completion of RT.

**aaa** Consider extended adjuvant neratinib following adjuvant trastuzumab-containing therapy for patients with HR-positive, HER2-positive disease with a perceived high risk of recurrence. The benefit or toxicities associated with extended neratinib in patients who have received pertuzumab or ado-trastuzumab emtansine is unknown.

---

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
SURVEILLANCE/FOLLOW-UP

Exam:
• History and physical exam 1–4 times per year as clinically appropriate for 5 y, then annually

Genetic screening:
• Periodic screening for changes in family history and genetic testing indications and referral to genetic counseling as indicated, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic

Post surgical management:
• Educate, monitor, and refer for lymphedema management, see NCCN Guidelines for Survivorship: Lymphedema.

Imaging:
• Mammography every 12 mo
• Routine imaging of reconstructed breast is not indicated

Screening for metastases:
• In the absence of clinical signs and symptoms suggestive of recurrent disease, there is no indication for laboratory or imaging studies for metastases screening

Endocrine therapy:
• Assess and encourage adherence to adjuvant endocrine therapy
• Women on tamoxifen: annual gynecologic assessment every 12 mo if uterus present
• Women on an aromatase inhibitor or who experience ovarian failure secondary to treatment should have monitoring of bone health with a bone mineral density determination at baseline and periodically thereafter

Lifestyle:
• Evidence suggests that active lifestyle, healthy diet, limited alcohol intake, and achieving and maintaining an ideal body weight (20–25 BMI) may lead to optimal breast cancer outcomes

Communication:
• Coordination of care between the primary care provider and specialists is encouraged. Additionally, a personalized survivorship treatment plan including personalized treatment summary of possible long-term toxicity and clear follow-up recommendations is recommended. See NCCN Guidelines for Survivorship

Engagement:
• Patients frequently require follow-up encouragement in order to improve adherence to ongoing screening and medication adherence

---

bbb Studies indicate that annual mammograms are the appropriate frequency for surveillance of breast cancer patients who have had breast-conserving surgery and RT with no clear advantage to shorter interval imaging. Patients should wait 6 to 12 months after the completion of RT to begin their annual mammogram surveillance. Suspicious findings on physical examination or surveillance imaging might warrant a shorter interval between mammograms.

ccc The use of estrogen, progesterone, or selective estrogen receptor modulators to treat osteoporosis or osteopenia in women with breast cancer is discouraged. The use of a bisphosphonate (oral/IV) or denosumab is acceptable to maintain or to improve bone mineral density and reduce risk of fractures in postmenopausal (natural or induced) patients receiving adjuvant endocrine therapy. Optimal duration of either therapy has not been established. Duration beyond 3 years is not known. Factors to consider for duration of anti-osteoporosis therapy include bone mineral density, response to therapy, and risk factors for continued bone loss or fracture. There are case reports of spontaneous fractures after denosumab discontinuation. Women treated with a bisphosphonate or denosumab should undergo a dental examination with preventive dentistry prior to the initiation of therapy, and should take supplemental calcium and vitamin D.
RECURRENT/STAGE IV (M1) DISEASE

CLINICAL STAGE

WORKUPa

- History and physical exam
- Discuss goals of therapy, adopt shared decision-making, and document course of care
- CBC
- Comprehensive metabolic panel, including liver function tests and alkaline phosphatase
- Chest diagnostic CT with contrast
- Abdominal ± pelvic diagnostic CT with contrast or MRI with contrast
- Brain MRI with contrast if suspicious CNS symptoms
- Spine MRI with contrast if back pain or symptoms of cord compression
- Bone scan or sodium fluoride PET/CT1 (category 2B)
- FDG PET/CTk,ddd (optional)
- X-rays of symptomatic bones and long and weight-bearing bones abnormal on bone scan
- First recurrence of disease should be biopsied
- Determination of tumor ER/PR and HER2 status on metastatic site
d,eee,fff
- For biomarker testing to identify candidates for additional targeted therapies, see Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R)
- Genetic counseling if patient is at risk for hereditary breast cancer

See Treatment of Local and Regional Recurrence (BINV-18) and Supportive careggg

See Systemic Treatment of Recurrent or Stage IV (M1) (BINV-19)hhh and Supportive careggg

---

a For tools to aid optimal assessment and management of older adults, see NCCN Guidelines for Older Adult Oncology.

d See Principles of Biomarker Testing (BINV-A).

e For risk criteria, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

1 Bone scan or sodium fluoride PET/CT may not be needed if FDG PET/CT is performed and clearly indicates bone metastasis, on both the PET and CT component.

k FDG PET/CT may also be helpful in identifying unsuspected regional nodal disease and/or distant metastases in locally advanced breast cancer when used in addition to standard staging studies.

ddd FDG PET/CT can be performed at the same time as diagnostic CT. FDG PET/CT is most helpful in situations where standard staging studies are equivocal or suspicious, especially in the setting of locally advanced or metastatic disease.

eee False-negative ER and/or PR determinations occur, and there may be discordance between the ER and/or PR determination between the primary and metastatic tumor(s). Therefore, endocrine therapy with its low attendant toxicity may be considered in patients with non-visceral or asymptomatic visceral tumors, especially in patients with clinical characteristics predicting for a hormone receptor-positive tumor (eg, long disease-free interval, limited sites of recurrence, indolent disease, older age).

fff In clinical situations where a biopsy cannot safely be obtained but the clinical evidence is strongly supportive of recurrence, treatment may commence based on the ER/PR/HER2 status of the primary tumor.

ggg See NCCN Guidelines for Palliative Care and NCCN Guidelines for Supportive Care.

hhh For the treatment of brain metastases, see NCCN Guidelines for Central Nervous System Cancers.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
**TREATMENT OF LOCAL AND REGIONAL RECURRENTCE**

**Local only recurrence**

- Initial treatment with lumpectomy + RT<sup>r</sup>
- Initial treatment with mastectomy + level I/II axillary dissection and prior RT
- Initial treatment with mastectomy and no prior RT

**Regional only or Local and regional recurrence**

- Supraclavicular recurrence
- Internal mammary node recurrence

**Total mastectomy + axillary lymph node staging if level I/II axillary dissection not previously done**<sup>iii</sup>

- Surgical resection if possible<sup>kkk</sup>
- Surgical resection if possible<sup>kkk</sup> + RT<sup>r</sup>
- Surgical resection if possible<sup>kkk</sup> + RT if possible<sup>lll</sup>
- RT if possible<sup>lll</sup>
- RT if possible<sup>lll</sup>
- RT if possible<sup>lll</sup>

**Consider systemic therapy**<sup>mmm</sup>

Preoperative/Adjuvant Chemotherapy (BINV-L)

Systemic Therapy for ER- and/or PR-Positive Recurrent or Stage IV (M1) Disease (BINV-P)

Chemotherapy Regimens for Recurrent or Stage IV (M1) Disease (BINV-Q)

---

<sup>†</sup> See Principles of Radiation Therapy (BINV-I).

<sup>iii</sup> Multidisciplinary approach is especially important in the management of breast cancer recurrence to consider all potential treatment options for optimal outcomes.

<sup>iii</sup> In women with a local breast recurrence after breast-conserving surgery who had a prior sentinel node biopsy (SNB), a repeat SNB may be considered although the accuracy of repeat SNB is unproven. On the other hand, the prognostic significance of repeat SNB after mastectomy is unknown and its use is discouraged.

<sup>kkk</sup> If not technically resectable, consider systemic therapy to best response, then resect if possible.

<sup>lll</sup> The decision to use RT to treat locoregional recurrence must factor in any prior radiation to the area and the risk of late normal tissue toxicity from the sum of the prior and planned radiation courses.

<sup>mmm</sup> See the Discussion for additional information.
SYSTEMIC TREATMENT OF RECURRENT OR STAGE IV (M1) DISEASE

Bone disease present

Add denosumab, zoledronic acid, or pamidronate

Bone disease not present

BINV-19

See BINV-20

ER- and/or PR-positive; HER2-negative

See BINV-22

ER- and/or PR-positive; HER2-positive

See BINV-24

ER- and PR-negative; HER2-positive

See BINV-25

ER- and PR-negative; HER2-negative

The role and timing of surgical removal of the primary tumor in patients presenting with de novo stage IV (M1) is the subject of ongoing investigations and must be individualized. Performance of local breast surgery and/or RT is reasonable in select patients responding to initial systemic therapy.

Denosumab, zoledronic acid, or pamidronate (all with calcium and vitamin D supplementation) should be given (category 1) in addition to chemotherapy or endocrine therapy if bone metastasis is present, expected survival is ≥3 months, and renal function is adequate. Patients should undergo a dental examination with preventive dentistry prior to initiation of this therapy. The optimal schedule for zoledronic acid is every 12 weeks.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

See Principles of Biomarker Testing (BINV-A).

Although patients with cancers with 1%–100% ER IHC staining are considered ER-positive and eligible for endocrine therapies, there are more limited data on the subgroup of cancers with ER-low–positive (1%–10%) results. The ER-low–positive group is heterogeneous with reported biologic behavior often similar to ER-negative cancers. This should be considered in decision-making for other adjuvant therapy and overall treatment pathway. See Principles of Biomarker Testing (BINV-A).
**SYSTEMIC TREATMENT OF RECURRENT OR STAGE IV (M1) DISEASE: ER- AND/OR PR-POSITIVE; HER2-NEGATIVE**

---

**See Principles of Biomarker Testing (BINV-A).**
SYSTEMIC TREATMENT OF RECURRENT OR STAGE IV (M1) DISEASE: ER- AND/OR PR-POSITIVE; HER2-NEGATIVE

Progression or unacceptable toxicity on first-line endocrine therapy

If not endocrine therapy refractory, consider:
- Additional line of endocrine therapy ± targeted therapy (see second-line therapy options on BINV-P)
- Systemic therapy
- For those with visceral crisis: Progression or unacceptable toxicity on first-line systemic therapy
  - Another line of systemic therapy

No clinical benefit after up to 3 sequential endocrine therapy regimens or Symptomatic visceral disease

Systemic therapy

Most patients will be candidates for multiple lines of systemic therapy to palliate advanced breast cancer. At each reassessment clinicians should assess value of ongoing treatment, the risks and benefits of an additional line of systemic therapy, patient performance status, and patient preferences through a shared decision-making process.

Consider no further cytotoxic therapy and Continue supportive care (See NCCN Guidelines for Palliative Care and NCCN Guidelines for Supportive Care)

- d See Principles of Biomarker Testing (BINV-A).
- v See Special Considerations for Breast Cancer in Men (BINV-J).
- eee False-negative ER and/or PR determinations occur, and there may be discordance between the ER and/or PR determination between the primary and metastatic tumor(s). Therefore, endocrine therapy with its low attendant toxicity may be considered in patients with non-visceral or asymptomatic visceral tumors, especially in patients with clinical characteristics predicting for a hormone receptor-positive tumor (eg, long disease-free interval, limited sites of recurrence, indolent disease, older age).
- qqq See Systemic Therapy Regimens for Recurrent or Stage IV (M1) Disease (BINV-Q).
- rrr See Systemic Therapy for ER- and/or PR-Positive Recurrent or Stage IV (M1) Disease (BINV-P).
- ttt See Principles of Monitoring Metastatic Disease (BINV-S).
- uuu If there is disease progression while on CDK4/6 inhibitor therapy, there are limited data to support an additional line of therapy with another CDK4/6-containing regimen. Likewise, if there is disease progression while on an everolimus-containing regimen, there are no data to support an additional line of therapy with another everolimus regimen.
- vvv The potential side effects of additional chemotherapy may outweigh any clinical benefit in a patient who has a compromised performance status. Patient preference must be taken into account.

Note: All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
SYSTEMIC TREATMENT OF RECURRENT OR STAGE IV (M1) DISEASE: ER- AND/OR PR-POSITIVE; HER2-POSITIVE

Systemic therapy + HER2-targeted therapy with:
- Pertuzumab + trastuzumab + taxane (preferred)
- Ado-trastuzumab emtansine (T-DM1)
- Fam-trastuzumab deruxtecan-nxki
- Trastuzumab + chemotherapy

Endocrine therapy ± HER2-targeted therapy (if premenopausal, consider ovarian ablation or suppression)

Other HER2-targeted therapies

Continue therapy until progression or unacceptable toxicity

If treatment was initiated with chemotherapy and trastuzumab + pertuzumab, and the chemotherapy was stopped, endocrine therapy may be added to trastuzumab + pertuzumab.

Fam-trastuzumab deruxtecan-nxki is indicated following two or more lines of prior HER2-targeted therapy in the metastatic setting. This agent is contraindicated for patients with pneumonitis or interstitial lung disease (ILD).

Trastuzumab given in combination with an anthracycline is associated with significant cardiac toxicity. Concurrent use of trastuzumab and pertuzumab with an anthracycline should be avoided.

For premenopausal women, selective ER modulators alone (without ovarian ablation/suppression) + HER2-targeted therapy is also an option.
Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

See Principles of Biomarker Testing (BINV-A).

False-negative ER and/or PR determinations occur, and there may be discordance between the ER and/or PR determination between the primary and metastatic tumor(s). Therefore, endocrine therapy with its low attendant toxicity may be considered in patients with non-visceral or asymptomatic visceral tumors, especially in patients with clinical characteristics predicting for a hormone receptor-positive tumor (eg, long disease-free interval, limited sites of recurrence, indolent disease, older age).

See Systemic Therapy Regimens for Recurrent or Stage IV (M1) Disease (BINV-Q).

See Systemic Therapy for ER- and/or PR-Positive Recurrent or Stage IV (M1) Disease (BINV-P).

See Principles of Monitoring Metastatic Disease (BINV-S).

Fam-trastuzumab deruxtecan-nxki is indicated following two or more lines of prior HER2-targeted therapy in the metastatic setting. This agent is contraindicated for patients with pneumonitis or interstitial lung disease (ILD).

Trastuzumab given in combination with an anthracycline is associated with significant cardiac toxicity. Concurrent use of trastuzumab and pertuzumab with an anthracycline should be avoided.

Patients previously treated with chemotherapy plus trastuzumab in the absence of pertuzumab may be considered for one line of therapy including both trastuzumab plus pertuzumab in combination with or without cytotoxic therapy (such as vinorelbine or taxane). Further research is needed to determine the ideal sequencing strategy for anti-HER2 therapy.

Continue HER2-targeted therapy following progression on first-line HER2-targeted chemotherapy for metastatic breast cancer. The optimal duration of trastuzumab in patients with long-term control of disease is unknown.

The potential side effects of additional HER2-targeted therapy may outweigh any clinical benefit in a patient who has a compromised performance status. Patient preference must be taken into account.

See NCCN Guidelines for Palliative Care

and

NCCN Guidelines for Supportive Care

\(^d\) See Principles of Biomarker Testing (BINV-A).

\(^qqq\) See Systemic Therapy Regimens for Recurrent or Stage IV (M1) Disease (BINV-Q).

\(^ttt\) See Principles of Monitoring Metastatic Disease (BINV-S).

\(^dddd\) The potential side effects of additional chemotherapy may outweigh any clinical benefit in a patient who has a compromised performance status. Patient preference must be taken into account.

\(^eeee\) See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
**PRINCIPLES OF BIOMARKER TESTING**

**HER2 TESTING**

- HER2 testing should be performed on all new primary or newly metastatic breast cancers using methodology outlined in the ASCO/CAP HER2 testing guideline.\(^a\)
- A re-review of the pathology with consideration for repeat or consultative HER2 testing should be made if a Grade 1 (any histologic type), pure mucinous, pure tubular, or pure cribriform carcinoma tests HER2-positive.\(^a\)
- After a negative HER2 test result on initial biopsy sample, consider retesting on subsequent surgical or other additional sample if the initial sample was suboptimal (e.g., minimal invasive cancer was present, cold ischemic time or fixation was suboptimal), testing error is expected, additional samples contain higher grade morphologically distinct cancer from the biopsy, to rule out heterogeneity in a high grade cancer, or if it will otherwise aid in clinical decision-making.\(^a\)

HER2 testing by validated IHC assay\(^b,c\)

- IHC 0,1+ → HER2 (-)  
- IHC 2+ → Equivocal result  
- IHC 3+ → HER2 (+)

Must reflex test with ISH (if same specimen), or order new test with IHC or dual probe ISH (if new specimen available).

HER2 testing by validated dual-probe\(^d\) ISH assay\(^b,c\)

- HER2-Negative:
  - (Group 5: HER2/CEP17 ratio <2.0 AND average HER2 copy number <4.0 signals/cell)
  - HER2-Negative\(^e\) (Determined by concurrent IHC and ISH results):
    - (Group 2) HER2/CEP17 ratio ≥2.0 AND average HER2 copy number <4.0 signals/cell and concurrent IHC 0-1+ or 2+
    - (Group 3) HER2/CEP17 ratio <2.0 AND average HER2 copy number ≥6.0 signals/cell and concurrent IHC 0-1+
    - (Group 4) HER2/CEP17 ratio <2.0 AND average HER2 copy number ≥4.0 and <6.0 signals/cell and concurrent IHC 0-1+ or 2+

- HER2-Positive:
  - (Group 2) HER2/CEP17 ratio ≥2.0 AND average HER2 copy number <4.0 signals/cell and concurrent IHC 3+
  - (Group 3) HER2/CEP17 ratio <2.0 AND average HER2 copy number ≥6.0 signals/cell and concurrent IHC 2+ or 3+
  - (Group 4) HER2/CEP17 ratio <2.0 AND average HER2 copy number ≥4.0 and <6.0 signals/cell and concurrent IHC 3+

HER2-Positive\(^e\) (Determined by concurrent IHC and ISH results):

- (Group 1: HER2/CEP17 ratio ≥2.0 AND average HER2 copy number ≥ 4.0 signals/cell)

\(^b\) Laboratory must participate in a quality assurance accreditation program for HER2 testing. Otherwise, tissue specimen should be sent to an accredited laboratory for testing. Health care systems and providers must cooperate to ensure the highest quality testing.

\(^c\) Evidence from trastuzumab adjuvant trials show that HER2 testing by ISH or IHC have similar utility to predict clinical benefit from HER2-targeted therapy.

\(^d\) Single-probe ISH assays are not preferentially recommended but if used, cases with average HER2 copy number ≥4.0 and <6.0 signals/cell should base final results on concurrent IHC and if 2+ reflexed to dual probe ISH testing. For ISH Groups 2–4 final ISH results are based on review of concurrent IHC, with recounting of the ISH test by a second reviewer if IHC is 2+ (per 2018 CAP/ASCO Update recommendations). Additional report comments are recommended for negative final results in these ISH Groups.

\(^e\) Additional report comments are recommended for negative final results in these ISH Groups.
Hormone receptor testing (ER and PR) by IHC should be performed on any new primary or newly metastatic breast cancer using methodology outlined in the latest ASCO/CAP hormone receptor testing guideline. DCIS should be tested for ER (PR not required).

ER testing should be used to determine if a patient is a candidate for endocrine therapies.

- Cancers with 1%–100% of cells positive for ER expression are considered ER-positive. Patients with these results are considered eligible for endocrine therapies (applies to DCIS and invasive cancers).
- Invasive cancers with between 1%–10% ER positivity are considered ER-low–positive. There are more limited data on the benefit of endocrine therapies in this group, but they suggest possible benefit from endocrine treatment, so patients are considered eligible for this treatment (as above). However, this group is noted to be heterogeneous and the biologic behavior of ER-low–positive cancers may be more similar to ER-negative cancers. This should be considered in decision-making for other adjuvant therapy and overall treatment pathway.
- Cancers with <1% staining are considered ER-negative. Patients with cancers with these results have not been shown to benefit from endocrine therapies.

Laboratories should have standard operating procedures to maximize accuracy and reproducibility of results for cases with <10% ER staining or weak intensity staining (to avoid false negatives). The status of controls should be reported for cases with these results.

PR testing by IHC on invasive cancers can aid in the prognostic classification of cancers and serve as a control for possible false-negative ER results. Patients with ER-negative, PR-positive cancers may be considered for endocrine therapies, but the data on this group are noted to be limited. The same overall interpretation principles apply but PR should be interpreted as either positive (if 1%–100% of cells have nuclear staining) or negative (if <1% or 0% of cells have nuclear staining).

Interpretation of any ER result by pathology should include evaluation of the concordance with the histologic findings of each case. Clinicians should be aware of when results are unusual and work with pathologists to attempt to resolve (eg, repeat testing, consultative review) or explain atypical reported findings. See table below.

PRINCIPLES OF DEDICATED BREAST MRI TESTING

See NCCN Guidelines for Breast Cancer Screening and Diagnosis for indications for screening MRI in women at increased breast cancer risk.

Personnel, Facility, and Equipment

• Breast MRI examinations are performed with IV contrast and should be performed and interpreted by an expert breast imaging team working in concert with the multidisciplinary treatment team.
• Breast MRI examinations require a dedicated breast coil and breast imaging radiologists familiar with the optimal timing sequences and other technical details for image interpretation. The imaging center should have the ability to perform MRI-guided needle sampling and/or image-guided localization of MRI-detected findings.

Clinical Indications and Applications

• May be used for staging evaluation to define extent of cancer or presence of multifocal or multicentric cancer in the ipsilateral breast, or as screening of the contralateral breast cancer at time of initial diagnosis (category 2B). There are no high-level data to demonstrate that the use of MRI to facilitate local therapy decision-making improves local recurrence or survival.\(^1\)
• May be helpful for breast cancer evaluation before and after preoperative systemic therapy to define extent of disease, response to treatment, and potential for breast-conserving therapy.
• May be useful for identifying primary cancer in women with axillary nodal adenocarcinoma and occult (or unidentified) primary cancer, with Paget’s disease, or with invasive lobular carcinoma poorly (or inadequately) defined on mammography, ultrasound, or physical examination.
• False-positive findings on breast MRI are common. Surgical decisions should not be based solely on the MRI findings. Additional tissue sampling of areas of concern identified by breast MRI is recommended.
• The utility of MRI in follow-up screening of women with prior breast cancer is undefined. It should generally be considered only in those whose lifetime risk of a second primary breast cancer is greater than 20% based on models largely dependent on family history, such as in those with the risk associated with inherited susceptibility to breast cancer.

FERTILITY AND BIRTH CONTROL

See NCCN Guidelines for Adolescent and Young Adult (AYA) Oncology

- All premenopausal patients should be informed about the potential impact of chemotherapy on fertility and asked about their desire for potential future pregnancies. Patients who may desire future pregnancies should be referred to fertility specialists before chemotherapy and/or endocrine therapy to discuss the options based on patient specifics, disease stage, and biology (which determine the urgency and type and sequence of treatment). Timing and duration allowed for fertility preservation, options inclusive of oocyte and embryo cryopreservation as well as evolving technologies, and the probability of successful pregnancies subsequent to completion of breast cancer therapy are also to be discussed.
- Although amenorrhea frequently occurs during or after chemotherapy, it appears that the majority of women younger than 35 years resume menses within 2 years of finishing adjuvant chemotherapy.
- Menses and fertility are not necessarily linked. Absence of regular menses, particularly if the patient is taking tamoxifen, does not necessarily imply lack of fertility. Conversely, the presence of menses does not guarantee fertility. There are limited data regarding continued fertility after chemotherapy.
- Patients should not become pregnant during treatment with RT, chemotherapy, endocrine therapy, or during or within 6 months of completing trastuzumab or pertuzumab.
- Although data are limited, hormone-based birth control is discouraged regardless of the hormone receptor status of the patient's cancer.
- Alternative methods of birth control include intrauterine devices (IUDs), barrier methods, or, for patients with no intent of future pregnancies, tubal ligation or vasectomy for the partner.
- Randomized trials have shown that ovarian suppression with GnRH agonist therapy administered during adjuvant chemotherapy in premenopausal women with breast tumors (regardless of hormone receptor status) may preserve ovarian function and diminish the likelihood of chemotherapy-induced amenorrhea.
- Breastfeeding following breast-conserving cancer treatment is not contraindicated. However, the quantity and quality of breast milk produced by the breast conserved may not be sufficient or may be lacking some of the nutrients needed. Breastfeeding is not recommended during active treatment with chemotherapy and endocrine therapy or within 6 months of completing trastuzumab or pertuzumab.
- Smaller historical experiences in patients with ER-positive disease have reported conflicting results with regard to the protective effect of GnRH agonist therapy on fertility.
Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
AXILLARY LYMPH NODE STAGING

SLNB should be performed and is the preferred method of axillary lymph node staging if the patient is an appropriate SLNB candidate (See BINV-D).

In the absence of definitive data demonstrating superior survival, the performance of axillary staging may be considered optional in patients who have particularly favorable tumors, patients for whom the selection of adjuvant systemic and/or RT is unlikely to be affected, the elderly, or those with serious comorbid conditions.

Level III dissection to the thoracic inlet should be performed only in cases with gross disease in level II and/or III. In the absence of gross disease in level II nodes, lymph node dissection should include tissue inferior to the axillary vein from the latissimus dorsi muscle laterally to the medial border of the pectoralis minor muscle (level I/II).

Lymphedema is a potential side effect after the treatment of axillary lymph node surgery resulting from damage to the lymphatic system. Early detection/diagnosis of lymphedema is key for optimal management. Consider pretreatment measurement of both arms as a baseline for patients with risk factors for lymphedema. See NCCN Guidelines for Survivorship: Lymphedema (SLYMPH-1).
MARGIN STATUS RECOMMENDATIONS FOR DCIS AND INVASIVE BREAST CANCER

- Margins should be evaluated on all surgical specimens from BCS. Requirements for optimal margin evaluation include:
  - Orientation of the surgical specimens
  - Description of the gross and microscopic margin status
  - Reporting of the distance, orientation, and type of tumor (invasive or DCIS) in relation to the closest margin.
- For mammographically detected DCIS with microcalcifications, complete resection should be documented by analysis of margins and specimen radiography. Post-excision mammography could also be performed whenever uncertainty about adequacy of excision remains.
- The NCCN Panel accepts the definitions of negative margins after breast conservation therapy from the 2014 SSO/ASTRO Margins Guideline for Stage I/II Invasive Cancers and the 2016 SSO/ASTRO/ASCO Guideline for DCIS. For patients with stage I or II invasive cancers after BCS, a positive margin is defined as “ink on tumor” (any invasive cancer or DCIS cells on ink). These patients generally require further surgery—either a re-excision to achieve a negative margin or a mastectomy. If re-excision is technically feasible to allow for BCS to achieve “no ink on tumor,” this can be done with resection of the involved margin guided by the orientation of the initial resection specimen or re-excision of the entire original excision cavity. There may be select patients with stage III invasive cancers who may be eligible for BCS. For these patients, the margins status would be accessed with similar definitions.

DCIS
- For patients with pure DCIS treated by BCS and WBRT, a quantitative description of any tumor close to margin resection width of at least 2 mm is associated with a reduced risk of ipsilateral breast tumor recurrence (IBTR) relative to narrower negative margin widths, while the routine practice of obtaining margins greater than 2 mm to further improve outcomes is not supported by the evidence. When there is only minimal or focal DCIS involvement near the margin, clinical judgment can be applied to determine if re-excision might be avoided in individual cases.
- For patients with DCIS treated with excision alone (no WBRT), regardless of margin width, there is a substantially higher rate of IBTR than treatment with excision and WBRT, even in predefined, low-risk patients. Although the optimal margin width for treatment with excision alone is unknown, it should be at least 2 mm, with some evidence suggesting improved IBTR rates with margin widths wider than 2 mm.
- DCIS with microinvasion (DCIS-M), defined as an invasive focus ≤1 mm in size, should refer to the DCIS margin definition when considering the optimal margin width (>2 mm), given that the majority of DCIS-M is comprised of DCIS and systemic therapy utilization for this lesion more closely reflects the treatment pattern for DCIS than for invasive carcinoma.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
MARGIN STATUS RECOMMENDATIONS FOR BOTH DCIS AND INVASIVE BREAST CANCER

Invasive Breast Cancer

- For invasive breast cancers that have a component of DCIS, regardless of the extent of DCIS, the negative margin definition of “no ink on tumor” should be based on the invasive margin guideline. In this setting, “no ink on tumor” is recommended for either DCIS or invasive cancer cells, primarily because the natural history, treatment, and outcomes of these lesions are more similar to invasive cancer than DCIS. Clinical judgment should be applied in specific cases for which following discussion with the patient, re-excision may be prudent.

- These margin recommendations cannot be applied directly to patients undergoing APBI,\(^1\) where data regarding local recurrence are more limited. Furthermore, individualized clinical judgment should be utilized on a case-by-case basis, using postoperative mammography to identify residual calcifications and clinical-pathologic factors such as quantitative extent of disease near margin, presence of extensive intraductal component (EIC), young age, or multiple close margins to assist in identifying patients who may have an increased risk of IBTR and therefore may be selected to benefit from re-excision.

- For patients with invasive breast cancer, after BCS if margin is microscopically focally positive, in the absence of an EIC,\(^3\) the use of a higher radiation boost dose to the tumor bed should be considered. A boost to the tumor bed is recommended in patients at higher risk for recurrence. Typical doses are 10–16 Gy at 2 Gy/fx.

---

\(^3\) EIC is defined as an infiltrating ductal cancer where greater than 25% of the tumor volume is DCIS and DCIS extends beyond the invasive cancer into surrounding normal breast parenchyma.

Note: All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
SPECIAL CONSIDERATIONS TO BREAST-CONSERVING THERAPY REQUIRING RADIATION THERAPY

Contraindications for breast-conserving therapy requiring RT include:

**Absolute**
- RT during pregnancy
- Diffuse suspicious or malignant-appearing microcalcifications
- Widespread disease that cannot be incorporated by local excision of a single region or segment of breast tissue that achieves negative margins with a satisfactory cosmetic result
- Diffusely positive pathologic margins\(^a\)
- Homozygous (biallelic inactivation) for ATM mutation (category 2B)

**Relative**
- Prior RT to the chest wall or breast; knowledge of doses and volumes prescribed is essential.
- Active connective tissue disease involving the skin (especially scleroderma and lupus)
- Positive pathologic margin\(^a\)
- Women with a known or suspected genetic predisposition to breast cancer:
  - May have an increased risk of ipsilateral breast recurrence or contralateral breast cancer with breast-conserving therapy
  - May be considered for prophylactic bilateral mastectomy for risk reduction
    (See NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast, Ovarian, and Pancreatic)
  - May have known or suspected Li-Fraumeni syndrome (category 2B)

---

\(^a\)See Margin Status Recommendations for DCIS and Invasive Breast Cancer (BINV-F).
PRINCIPLES OF BREAST RECONSTRUCTION FOLLOWING SURGERY

• Breast reconstruction may be an option for any woman receiving surgical treatment for breast cancer. All women undergoing breast cancer treatment should be educated about breast reconstructive options as adapted to their individual clinical situation. However, breast reconstruction should not interfere with the appropriate surgical management of the cancer or the scope of appropriate surgical treatment for this disease. Coordinating consultation and surgical treatment with a reconstructive surgeon should be executed within a reasonable time frame. The process of breast reconstruction should not govern the timing or the scope of appropriate surgical treatment for this disease. The availability of or the practicality of breast reconstruction should not result in the delay or refusal of appropriate surgical intervention.

• An evaluation of the likely cosmetic outcome of lumpectomy should be performed prior to surgery. Oncoplastic techniques for breast conservation can extend breast-conserving surgical options in situations where the resection by itself would likely yield an unacceptable cosmetic outcome. Application of these procedures may reduce the need for mastectomy and reduce the chances of secondary surgery for re-excision while minimizing breast deformity. Patients should be informed of the possibility of positive margins and potential need for secondary surgery, which could include re-excision segmental resection, or could require mastectomy with or without loss of the nipple. Oncoplastic procedures can be combined with surgery on the contralateral unaffected breast to minimize long-term asymmetry.

• For mastectomy, the possibility of reconstruction should be discussed and a preoperative evaluation of reconstructive options should be considered. Surgical options for breast reconstruction following mastectomy include:
  ‣ Procedures that incorporate breast implants (ie, tissue expander placement followed by implant placement, immediate implant placement)
  ‣ Procedures that incorporate autologous tissue transplantation (ie, pedicled TRAM flap, fat grafting, various microsurgical flaps from the abdomen, back, buttocks, and thigh)
  ‣ Procedures that incorporate both breast implants and autologous tissue transplantation (eg, latissimus dorsi flaps)

• Breast reconstruction following mastectomy can commence at the same time as mastectomy (“immediate”) or at some time following the completion of cancer treatment (“delayed”). In many cases, breast reconstruction involves a staged approach requiring more than one procedure such as:
  ‣ Surgery on the contralateral breast to improve symmetry
  ‣ Revision surgery involving the breast and/or donor site
  ‣ Nipple and areola reconstruction and tattoo pigmentation

• As with any mastectomy, there is a risk of local and regional cancer recurrence, and evidence suggests skin-sparing mastectomy is probably equivalent to standard mastectomy in this regard. Skin-sparing mastectomy should be performed by an experienced breast surgery team that works in a coordinated, multidisciplinary fashion to guide proper patient selection for skin-sparing mastectomy, determine optimal sequencing of the reconstructive procedure(s) in relation to adjuvant therapies, and perform a resection that achieves appropriate surgical margins. Post-mastectomy radiation should still be applied in cases treated by skin-sparing mastectomy following the same selection criteria as for standard mastectomy.

• Immediate reconstruction is contraindicated in the setting of mastectomy for IBC due to the high risk of recurrence, aggressive nature of the disease, and consequent need to proceed expeditiously to postoperative radiotherapy for local control without any potential delay. As skin-sparing mastectomy has not yet been demonstrated to be safe for IBC, there is also a need to resect currently or previously involved skin at the time of mastectomy. Thus, there is no advantage to immediate reconstruction in this setting.

Continued
PRINCIPLES OF BREAST RECONSTRUCTION FOLLOWING SURGERY

- In general, the nipple-areolar complex (NAC) is sacrificed with skin-sparing mastectomy for cancer therapy. However, NAC-sparing procedures may be an option in cancer patients who are carefully selected by experienced multidisciplinary teams. Retrospective data support the use of NAC-sparing procedures for breast cancer therapy with low nipple-involvement rates, comparable local recurrence rates, and low complication rates for early-stage and locally advanced invasive cancers and/or DCIS in patients with small to moderate breast volume and minimal to moderate ptosis (acceptable preoperative nipple position). Preoperative clinical evidence of nipple involvement, including Paget's disease, nipple discharge associated with malignancy, and/or imaging findings suggesting malignant involvement of the nipple or subareolar tissues contraindicates nipple preservation. Nipple margin assessment is mandatory, and the nipple margin should be clearly designated.

- Reconstruction may be performed in the previously radiated patient (delayed reconstruction after mastectomy and radiation or immediate reconstruction in patients undergoing mastectomy after previous breast conservation). In patients undergoing delayed reconstruction after mastectomy and radiation, autologous tissue reconstruction is preferred. Tissue expander/implant-based reconstruction in this setting can result in a significantly increased risk of capsular contracture, malposition, poor cosmesis, implant exposure, and failed reconstruction.

- In patients undergoing mastectomy after previous breast conservation therapy, implant-based reconstruction results in higher complication rates than autologous tissue reconstruction but may be considered in appropriately selected patients based on preoperative factors and intraoperative considerations.

- While noninflammatory, locally advanced breast cancer is not an absolute contraindication to immediate reconstruction, post-mastectomy radiation should still be applied regardless of the reconstruction approach:
  - When post-mastectomy radiation is required and autologous tissue reconstruction is planned, reconstruction is either delayed until after the completion of RT, or it can be initiated at the time of mastectomy with tissue expander placement followed by autologous tissue reconstruction. While some experienced breast cancer teams have employed protocols in which immediate tissue reconstructions are followed by RT, it is generally preferred that the RT precede the placement of the autologous tissue, because of reported loss in reconstruction cosmesis (category 2B).
  - When implant reconstruction is planned in a patient requiring RT, a staged approach with immediate tissue expander placement followed by implant placement is preferred. Surgery to exchange the tissue expanders with permanent implants can be performed prior to radiation or after completion of RT. Direct-to-implant reconstruction in patients requiring postoperative radiation can be considered in appropriately selected patients based on preoperative and intraoperative considerations.

- Reconstruction selection is based on an assessment of cancer treatment, patient body habitus, obesity, smoking history, comorbidities, and patient concerns. Smoking and obesity increase the risk of complications for all types of breast reconstruction whether with implant or flap. Smoking and obesity are therefore considered a relative contraindication to breast reconstruction and patients should be made aware of increased rates of wound healing complications and partial or complete flap failure among smokers and obese patients.

- Women who are not satisfied with the cosmetic outcome following completion of breast cancer treatment should be offered a plastic surgery consultation.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Optimizing Delivery of Individual Therapy
- It is important to individualize RT planning and delivery.
  - CT-based treatment planning is encouraged to delineate target volumes and adjacent organs at risk.
  - Radiation to the breast/chest wall and nodal regions is generally delivered with photons ± electrons.
  - Greater target dose homogeneity and sparing of normal tissues can be accomplished using compensators such as wedges, forward planning using segments, and intensity-modulated RT (IMRT).
  - Respiratory control techniques including deep inspiration breath-hold and prone positioning may be used to try to further reduce dose to adjacent heart and lung and adjacent normal tissue.
  - Boost treatment in the setting of breast conservation can be delivered using enface electrons, photons, or brachytherapy. Chest wall scar boost when indicated is typically treated with electrons or photons.
  - Verification of daily setup consistency is done with weekly imaging. When using certain techniques (ie, prone breast), more frequent imaging may be appropriate. Routine use of daily imaging is not recommended.

Whole Breast Radiation
- Target definition is the breast tissue in entirety.
- RT dosing:
  - The whole breast should receive a dose of 45–50.4 Gy in 25–28 fractions or 40–42.5 Gy in 15–16 fractions (hypofractionation is preferred).
  - A boost to the tumor bed is recommended in patients at higher risk for recurrence. Typical boost doses are 10–16 Gy in 4–8 fractions.
  - All dose schedules are given 5 days per week.

Chest Wall Radiation (including breast reconstruction)
- The target includes the ipsilateral chest wall, mastectomy scar, and drain sites when indicated.
  - Depending on whether or not the patient has had breast reconstruction, several techniques using photons and/or electrons are appropriate.
  - CT-based treatment planning is encouraged in order to identify lung and heart volumes and minimize exposure of these organs.
  - Special consideration should be given to the use of bolus material to ensure that the skin dose is adequate.
- RT dosing:
  - Dose is 45–50.4 Gy in 25–28 fractions to the chest wall ± scar boost, at 1.8–2 Gy per fraction, to a total dose of approximately 60 Gy.
  - All dose schedules are given 5 days per week.

Regional Nodal Radiation
- Target delineation is best achieved by the use of CT-based treatment planning.
  - For the paraclavicular and axillary nodes, prescription depth varies based on the patient anatomy.
  - For internal mammary node identification, the internal mammary artery and vein can be used as a surrogate for the nodal location (as the nodes themselves are not usually visible on planning imaging). Based on the post-mastectomy radiation randomized studies and recent trials, RT of the internal mammary nodal chain to include the first 3 intercostal spaces should be strongly considered when delivering regional nodal irradiation. When treating the internal mammary nodes, dose-volume histograms (DVHs) should be used to evaluate dose constraints, dose to normal tissues (ie, heart, lung), and planned target volumes (PTVs).
- RT dosing:
  - Dose is 45–50.4 Gy in 25–28 fractions to the regional nodal fields.
  - All dose schedules are given 5 days per week.

Accelerated Partial Breast Irradiation (APBI)
- Studies of APBI suggest that rates of local control in selected low-risk patients with early-stage breast cancer may be comparable to those treated with standard WBRT. However, compared to standard WBRT, several studies document an inferior cosmetic outcome with APBI. Follow-up is limited and studies are ongoing.
  - Patients are encouraged to participate in clinical trials.
  - The NCCN Panel accepts the updated 2016 version of the ASTRO APBI guideline, which now defines patients "suitable" for APBI to be one of the following:
    - 1) ≥50 years with invasive ductal carcinoma measuring ≤2 cm (T1 disease) with negative margin widths of ≥2 mm, no LVI, ER-positive, and BRCA negative; or
    - 2) low/intermediate nuclear grade, screening-detected DCIS measuring size ≤2.5 cm with negative margin widths of ≥3 mm.
- RT dosing:
  - A course of 34 Gy in 10 fractions delivered twice per day with brachytherapy or 38.5 Gy in 10 fractions delivered twice per day with external beam photon therapy is typically prescribed to the tumor bed.
  - Other fractionation schemes are currently under investigation.

Preoperative Systemic Therapy
- In patients treated with preoperative systemic therapy, adjuvant RT is based on the maximal disease stage (ie, clinical stage, pathologic stage, tumor characteristics) at diagnosis (before preoperative systemic therapy) and pathology results after preoperative systemic therapy.
SPECIAL CONSIDERATIONS FOR BREAST CANCER IN MEN

• Few men have been included in breast cancer trials.¹ Therefore, recommendations regarding management of breast cancer in men are generally extrapolated from findings of clinical trials focusing on breast cancer in women.

• Although there are some biologic and clinical differences between breast cancer in men and women, management of breast cancer in men is similar overall to management of breast cancer in women, with the following special considerations pertinent to male patients:²

  ▶ Genetics: The NCCN Panel recommends consideration of genetic testing for all men with breast cancer (See NCCN Guidelines for Genetic/Familial High Risk Assessment: Breast, Ovarian, and Pancreatic).

  ▶ Breast surgery: Historically, men with breast cancer have undergone mastectomy more often than breast-conserving surgery. However, breast-conserving therapy is increasingly being performed in men and evolving data indicate that breast conservation in men is associated with equivalent outcomes to mastectomy and that it is safe and feasible. Decisions about breast conservation versus mastectomy in men should be made according to similar criteria as for women.²⁻⁹

  ▶ Axillary lymph node surgery: As in women, SLNB should be performed in the setting of male breast cancer with a clinically node-negative axilla.²⁻⁴

  ▶ RT: Indications for radiation after breast surgery in men with breast cancer are the same as for women with breast cancer.²⁻⁵⁻¹⁰⁻¹¹

  ▶ Use of molecular assays: Data are limited regarding the use of molecular assays to assess prognosis and to predict benefit from chemotherapy in men with breast cancer.² Available data suggest the 21-gene assay recurrence score provides prognostic information in men with breast cancer.¹²⁻¹³

  ▶ Preoperative/adjuvant systemic therapy: Chemotherapy with/without HER2-targeted therapy should be recommended for men with breast cancer according to guidelines for women with breast cancer.² Options for adjuvant endocrine therapy for men with breast cancer include tamoxifen for 5–10 years or, if tamoxifen is contraindicated, a GnRH analog plus an aromatase inhibitor. In men, single-agent adjuvant treatment with an aromatase inhibitor has been associated with inferior outcomes compared to tamoxifen alone, likely due to inadequate estradiol suppression, and is not recommended.²⁻¹⁴⁻¹⁷

  ▶ Follow-up after treatment for early-stage disease: Routine mammography is not required after treatment for early breast cancer in men.² The NCCN Panel recommends that bone density be assessed at baseline and every 2 years in men with breast cancer who receive adjuvant GnRH analog therapy. Low bone density should be managed according to standard guidelines.¹⁸

  ▶ Systemic therapy for advanced disease: Management of advanced breast cancer in men is similar to that in women; however, it is preferred that when an aromatase inhibitor is used, a GnRH analog should be given concurrently.² Available data suggest single-agent fulvestrant has similar efficacy in men as in women.¹⁹ Newer agents such as CDK4/6 inhibitors in combination with an aromatase inhibitor or fulvestrant, mTOR inhibitors, and PIK3CA inhibitors have not been systematically evaluated in clinical trials in men with breast cancer. However, available real-world data suggest comparable efficacy and safety profiles and it is reasonable to recommend these agents to men based on extrapolation of data from studies comprised largely of female participants with advanced breast cancer. Indications for and recommendations regarding chemotherapy for advanced breast cancer in men are similar to those for advanced breast cancer in women.¹

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### Notes

- **a** If patient is not postmenopausal, sequential evaluation of hormonal status is recommended to consider an alternative endocrine agent. 
- **b** See Definition of Menopause (BINV-O).
- **c** A balanced discussion of the risks and benefits associated with ovarian suppression therapy is critical. Aromatase inhibitor or tamoxifen for 5 y plus ovarian suppression should be considered, based on SOFT and TEXT clinical trial outcomes, for premenopausal women at higher risk of recurrence (ie, young age, high-grade tumor, lymph node involvement).
- **d** The three selective aromatase inhibitors (ie, anastrozole, letrozole, exemestane) have shown similar anti-tumor efficacy and toxicity profiles in randomized studies in the adjuvant and preoperative settings. The optimal duration of aromatase inhibitors in adjuvant therapy is uncertain.
- **e** Some SSRIs like fluoxetine and paroxetine decrease the formation of endoxifen, 4-OH tamoxifen, and active metabolites of tamoxifen, and may impact its efficacy. Caution is advised about coadministration of these drugs with tamoxifen. However, citalopram and venlafaxine appear to have minimal impact on tamoxifen metabolism. At this time, based on current data the panel recommends against CYP2D6 gene testing for women being considered for tamoxifen therapy. Coadministration of strong inhibitors of CYP2D6 should be used with caution.

---

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
PREOPERATIVE/ADJUVANT THERAPY REGIMENS

HER2-Negative

**Preferred Regimens:**
- Dose-dense AC (doxorubicin/cyclophosphamide) followed by paclitaxel every 2 weeks
- Dose-dense AC (doxorubicin/cyclophosphamide) followed by weekly paclitaxel
- TC (docetaxel and cyclophosphamide)
- If triple-negative breast cancer (TNBC) and residual disease after preoperative therapy with taxane-, alkylator-, and anthracycline-based chemotherapy: capecitabine

**Useful in Certain Circumstances:**
- Dose-dense AC (doxorubicin/cyclophosphamide)
- AC (doxorubicin/cyclophosphamide) every 3 weeks (category 2B)
- CMF (cyclophosphamide/methotrexate/fluorouracil)
- AC followed by weekly paclitaxel

**Other Recommended Regimens:**
- AC followed by docetaxel every 3 weeks
- EC (epirubicin/cyclophosphamide)
- TAC (docetaxel/doxorubicin/cyclophosphamide)
- Select patients with TNBC in the preoperative setting only:
  - Weekly paclitaxel + carboplatin
  - Docetaxel + carboplatin

**Notes:**
- Retrospective evidence suggests that anthracycline-based chemotherapy regimens may be superior to non-anthracycline-based regimens in patients with HER2-positive tumors.
- Randomized clinical trials demonstrate that the addition of a taxane to anthracycline-based chemotherapy provides an improved outcome.
- CMF and RT may be given concurrently, or the CMF may be given first. All other chemotherapy regimens should be given prior to radiotherapy.
- Chemotherapy and endocrine therapy used as adjuvant therapy should be given sequentially with endocrine therapy following chemotherapy.
- Nab-paclitaxel may be substituted for paclitaxel or docetaxel due to medical necessity (ie, hypersensitivity reaction). If substituted for weekly paclitaxel or docetaxel, then the weekly dose of nab-paclitaxel should not exceed 125 mg/m².
- Consider scalp cooling to reduce incidence of chemotherapy-induced alopecia for patients receiving neoadjuvant/adjuvant chemotherapy. Results may be less effective with anthracycline-containing regimens.
- The regimens listed for HER2-negative disease are all category 1 (except where indicated) when used in the adjuvant setting.

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
### Preferred Regimens:

**HER2-Positive**

- AC followed by T + trastuzumab\(^k, n\) (doxorubicin/cyclophosphamide followed by paclitaxel plus trastuzumab, various schedules)
- AC followed by T + trastuzumab\(^k\) + pertuzumab\(^n\) (doxorubicin/cyclophosphamide followed by paclitaxel plus trastuzumab plus pertuzumab)
- Paclitaxel + trastuzumab\(^k, o\)
- TCH (docetaxel/carboplatin/trastuzumab\(^k\))
- TCHP (docetaxel/carboplatin/trastuzumab/pertuzumab\(^h\))
  - If no residual disease after preoperative therapy or no preoperative therapy: Complete up to one year of HER2-targeted therapy with trastuzumab\(^k\) (category 1) ± pertuzumab.\(^p\)
  - If residual disease after preoperative therapy: Ado-trastuzumab emtansine (category 1) alone\(^q\) If ado-trastuzumab emtansine discontinued for toxicity, then trastuzumab\(^k\) (category 1) ± pertuzumab to complete one year of therapy.\(^p\)

### Useful in Certain Circumstances:

- Docetaxel + cyclophosphamide + trastuzumab\(^k\)

### Other Recommended Regimens:

- AC followed by docetaxel + trastuzumab\(^k, n\) (doxorubicin/cyclophosphamide followed by docetaxel + trastuzumab)
- AC followed by docetaxel + trastuzumab\(^k\) + pertuzumab\(^n\) (doxorubicin/cyclophosphamide followed by docetaxel + trastuzumab + pertuzumab)

---

\(a\) Retrospective evidence suggests that anthracycline-based chemotherapy regimens may be superior to non-anthracycline-based regimens in patients with HER2-positive tumors.

\(b\) Randomized clinical trials demonstrate that the addition of a taxane to anthracycline-based chemotherapy provides an improved outcome.

\(c\) CMF and RT may be given concurrently, or the CMF may be given first. All other chemotherapy regimens should be given prior to radiotherapy.

\(d\) Chemotherapy and endocrine therapy used as adjuvant therapy should be given sequentially with endocrine therapy following chemotherapy.

\(e\) Nab-paclitaxel may be substituted for paclitaxel or docetaxel due to medical necessity (ie, hypersensitivity reaction). If substituted for weekly paclitaxel or docetaxel, then the weekly dose of nab-paclitaxel should not exceed 125 mg/m\(^2\).

\(f\) Consider scalp cooling to reduce incidence of chemotherapy-induced alopecia for patients receiving chemotherapy. Results may be less effective with anthracycline-containing regimens.

\(g\) An FDA-approved biosimilar is an appropriate substitute for trastuzumab.

\(h\) Trastuzumab and hyaluronidase-xxxf injection for subcutaneous use may be substituted anywhere that the combination of intravenous pertuzumab and intravenous trastuzumab are given as part of systemic therapy. Pertuzumab, trastuzumab, and hyaluronidase-xxxf injection for subcutaneous use has different dosing and administration instructions compared to the intravenous products.

\(i\) Trastuzumab given in combination with an anthracycline is associated with significant cardiac toxicity. Concurrent use of trastuzumab and pertuzumab with an anthracycline should be avoided.

\(j\) Paclitaxel + trastuzumab may be considered for patients with low-risk T1,N0,M0, HER2-positive disease, particularly those not eligible for other standard adjuvant regimens due to comorbidities.

\(k\) Pertuzumab, trastuzumab, and hyaluronidase-xxxf injection for subcutaneous use may be substituted anywhere that the combination of intravenous pertuzumab and intravenous trastuzumab are given as part of systemic therapy. Pertuzumab, trastuzumab, and hyaluronidase-xxxf injection for subcutaneous use has different dosing and administration instructions compared to the intravenous products.

\(l\) Consider extended adjuvant neratinib following adjuvant trastuzumab-containing therapy for patients with HR-positive, HER2-positive disease with a perceived high risk of recurrence. The benefit or toxicities associated with extended neratinib in patients who have received pertuzumab or ado-trastuzumab emtansine is unknown.

### PREOPERATIVE/ADJUVANT THERAPY REGIMENS

#### HER2-Negative - Preferred Regimens:
- **Dose-dense AC followed by paclitaxel**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 14 days for 4 cycles.
  - Paclitaxel 175 mg/m² by 3 h IV infusion day 1
    - Cycled every 14 days for 4 cycles.
- **Dose-dense AC followed by weekly paclitaxel**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 14 days for 4 cycles.
  - Paclitaxel 80 mg/m² by 1 h IV infusion weekly for 12 weeks.
- **TC**
  - Docetaxel 75 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 21 days for 4 cycles.

#### HER2-Negative - Useful in Certain Circumstances:
- **Dose-dense AC**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 14 days for 4 cycles.
- **AC**
  - Doxorubicin 60 mg/m² IV on day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 21 days for 4 cycles.
- **CMF chemotherapy**
  - Cyclophosphamide 100 mg/m² PO days 1–14
  - Methotrexate 40 mg/m² IV days 1 & 8
  - 5-fluorouracil 600 mg/m² IV days 1 & 8
    - Cycled every 28 days for 6 cycles.
- **AC followed by weekly paclitaxel**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 21 days for 4 cycles.
    - Followed by:
      - Paclitaxel 80 mg/m² by 1 h IV infusion weekly for 12 weeks.
- **Weekly paclitaxel + carboplatin**
  - Paclitaxel 80 mg/m² days 1, 8, and 15
  - Carboplatin AUC 6 day 1
    - Cycled every 21 days x 4 cycles.
- **Docetaxel + carboplatin (4–6 cycles)**
  - Docetaxel 75 mg/m² day 1
  - Carboplatin AUC 6 day 1
    - Cycled every 21 days x 4–6 cycles.

#### HER2-Negative - Other Recommended Regimens:
- **AC followed by docetaxel every 3 weeks**
  - Doxorubicin 60 mg/m² IV on day 1
  - Cyclophosphamide 600 mg/m² IV day 1
    - Cycled every 21 days for 4 cycles.
  - Followed by:
    - Docetaxel 100 mg/m² IV on day 1
      - Cycled every 21 days for 4 cycles.
- **EC chemotherapy**
  - Epirubicin 100 mg/m² IV day 1
  - Cyclophosphamide 830 mg/m² IV day 1
    - Cycled every 21 days for 8 cycles.
- **TAC chemotherapy**
  - Docetaxel 75 mg/m² IV day 1
  - Doxorubicin 50 mg/m² IV day 1
  - Cyclophosphamide 500 mg/m² IV day 1
    - Cycled every 21 days for 6 cycles.

---

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

---

All cycles are with myeloid growth factor support. See NCCN Guidelines for Hematopoietic Growth Factors.
### HER2-Positive - Preferred regimens:

- **AC followed by T + trastuzumab**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Paclitaxel 80 mg/m² by 1 h IV weekly for 12 wks
  - Followed by:
    - Trastuzumab 4 mg/kg IV with first dose of paclitaxel
    - Followed by:
      - Trastuzumab 2 mg/kg IV weekly to complete 1 y of therapy
    - As an alternative, trastuzumab 6 mg/kg IV every 21 days may be used following the completion of paclitaxel, and given to complete 1 y of trastuzumab treatment.

- **AC followed by T + trastuzumab + pertuzumab**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Paclitaxel 80 mg/m² IV days 1, 8, and 15
  - Followed by:
    - Pertuzumab 840 mg IV day 1 followed by 420 mg IV
    - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV
    - Paclitaxel 80 mg/m² IV day 1
  - Followed by:
    - Trastuzumab 6 mg/kg IV day 1
    - Pertuzumab 420 mg IV day 1
  - Followed by:
    - Trastuzumab 2 mg/kg IV weekly to complete 1 y of therapy

- **Paclitaxel + trastuzumab**
  - Paclitaxel 80 mg/m² IV weekly for 12 weeks
  - Followed by:
    - Trastuzumab 4 mg/kg IV with first dose of paclitaxel
    - Followed by:
      - Trastuzumab 2 mg/kg IV weekly to complete 1 y of therapy
    - As an alternative, trastuzumab 6 mg/kg IV every 21 days may be used following the completion of paclitaxel, and given to complete 1 y of trastuzumab treatment.

- **Dose-dense AC followed by paclitaxel + trastuzumab**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Paclitaxel 175 mg/m² by 3 h IV infusion day 1
  - Followed by:
    - Paclitaxel 175 mg/m² by 3 h IV infusion day 1
    - Cycled every 14 days for 4 cycles
  - With:
    - Paclitaxel 80 mg/m² IV weekly for 12 wks
    - Trastuzumab 8 mg/kg IV day 1
    - Followed by:
      - Paclitaxel 80 mg/m² IV weekly for 12 wks
      - Trastuzumab 8 mg/kg IV wk 1
    - Followed by:
      - Paclitaxel 80 mg/m² IV weekly for 12 wks
      - Trastuzumab 6 mg/kg IV wk 1
      - Cycled every 21 days to complete 1 y of therapy

- **TCH**
  - Docetaxel 75 mg/m² IV day 1
  - Carboplatin AUC 6 IV day 1
    - Cycled every 21 days for 6 cycles
    - With:
      - Trastuzumab 4 mg/kg IV wk 1
      - Trastuzumab 2 mg/kg IV for 17 wks
    - Followed by:
      - Trastuzumab 6 mg/kg IV wk 1
      - Cycled every 21 days to complete 1 y of therapy

- **TCH + pertuzumab**
  - Docetaxel 75 mg/m² IV day 1
  - Carboplatin AUC 6 IV day 1
    - Cycled every 21 days for 6 cycles
    - With:
      - Trastuzumab 8 mg/kg IV day 1
      - Pertuzumab 840 mg IV day 1
    - Followed by:
      - Trastuzumab 6 mg/kg IV on day 1
      - Pertuzumab 420 mg IV day 1
    - Cycled every 21 days to complete 1 y of therapy

- **TCH + trastuzumab + pertuzumab**
  - Docetaxel 75 mg/m² IV day 1
  - Carboplatin AUC 6 IV day 1
    - Cycled every 21 days for 6 cycles
    - With:
      - Trastuzumab 100 mg/m² IV day 1
      - Pertuzumab 420 mg IV day 1
    - Followed by:
      - Trastuzumab 6 mg/kg IV wk 1
      - Cycled every 21 days to complete 1 y of therapy

### Note:

- All cycles are with myeloid growth factor support. See NCCN Guidelines for Hematopoietic Growth Factors.
- Evaluate left ventricular ejection fraction (LVEF) prior to and during treatment.
- The optimal frequency of LVEF assessment during adjuvant trastuzumab therapy is not known. The FDA label recommends LVEF measurements prior to initiation of trastuzumab and every 3 mo during therapy.
The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### HER2-Positive**k,l** - Useful in Certain Circumstances:

- **Docetaxel/cyclophosphamide + trastuzumab**
  - Docetaxel 75 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Cycled every 21 days for 4 cycles
  - With:
    - Trastuzumab 4 mg/kg IV wk 1
    - Followed by
    - Trastuzumab 2 mg/kg IV weekly for 11 wks
    - Followed by
    - Trastuzumab 6 mg/kg IV
  - Cycled every 21 days to complete 1 y of therapy of trastuzumab therapy.

OR

- Trastuzumab 8 mg/kg IV wk 1
  - Followed by:
  - Trastuzumab 6 mg/kg IV every 21 days to complete 1 y of trastuzumab therapy

### HER2-Positive**k,l,m** - Other Recommended Regimens:

- **AC followed by docetaxel + trastuzumab**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Cycled every 21 days for 4 cycles
  - With:
    - Trastuzumab 4 mg/kg IV wk 1
    - Followed by:
    - Trastuzumab 2 mg/kg IV weekly for 11 wks
    - Followed by:
    - Trastuzumab 6 mg/kg IV
  - Cycled every 21 days to complete 1 y of trastuzumab therapy.

- **AC followed by docetaxel + trastuzumab + pertuzumab**
  - Doxorubicin 60 mg/m² IV day 1
  - Cyclophosphamide 600 mg/m² IV day 1
  - Cycled every 21 days for 4 cycles
  - Followed by:
    - Pertuzumab 840 mg IV day 1 followed by 420 mg IV
    - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV
    - Docetaxel 75–100 mg/m² IV day 1
  - Cycled every 21 days for 4 cycles
  - Followed by:
    - Pertuzumab 6 mg/kg IV
    - Trastuzumab 420 mg IV day 1
  - Cycled every 21 days to complete 1 y of therapy.

**m** Pertuzumab, trastuzumab, and hyaluronidase-zzxf injection for subcutaneous use may be substituted anywhere that the combination of intravenous pertuzumab and intravenous trastuzumab are given as part of systemic therapy. Pertuzumab, trastuzumab, and hyaluronidase-zzxf injection for subcutaneous use has different dosing and administration instructions compared to the intravenous products.

**s** Evaluate LVEF prior to and during treatment. The optimal frequency of LVEF assessment during adjuvant trastuzumab therapy is not known. The FDA label recommends LVEF measurements prior to initiation of trastuzumab and every 3 mo during therapy.

**k** An FDA-approved biosimilar is an appropriate substitute for trastuzumab.

**l** Trastuzumab and hyaluronidase-oysk injection for subcutaneous use may be substituted for trastuzumab. It has different dosage and administration instructions compared to intravenous trastuzumab. Do not substitute trastuzumab and hyaluronidase-oysk for or with ado-trastuzumab emtansine.

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.
REFERENCES FOR PREOPERATIVE/ADJUVANT THERAPY REGIMENS

PRINCIPLES OF PREOPERATIVE SYSTEMIC THERAPY

Known Benefits of Preoperative Systemic Therapy

- Facilitates breast conservation
- Can render inoperable tumors operable
- Provides important prognostic information at an individual patient level based on response to therapy, particularly in patients with triple-negative (TNBC) and HER2-positive breast cancer
- Allows the modification or addition of adjuvant regimens among patients with HER2-positive and TNBC with residual disease
- Allows time for genetic testing
- Allows time to plan breast reconstruction in patients electing mastectomy

Opportunities

- May allow SLNB alone if a positive axilla is cleared with therapy
- May provide an opportunity to modify systemic treatment if no preoperative therapy response or progression of disease
- May allow for smaller radiotherapy ports or less radiotherapy if axillary nodal disease cleared
- Excellent research platform to test novel therapies and predictive biomarkers

Cautions

- Possible overtreatment with systemic therapy if clinical stage is overestimated
- Possible undertreatment locoregionally with radiotherapy if clinical stage is underestimated
- Possibility of disease progression during preoperative systemic therapy

Candidates for Preoperative Systemic Therapy

- Patients with inoperable breast cancer:
  - IBC
  - Bulky or matted N2 axillary nodes
  - N3 nodal disease
  - T4 tumors
- In patients with operable breast cancer, preoperative systemic therapy is preferred for those with:
  - HER2-positive disease and TNBC, if T ≥2 or N ≥1
  - Large primary tumor relative to breast size in a patient who desires breast conservation
  - With node-positive disease likely to become node-negative with preoperative systemic therapy
  - If time needed to decide surgical options

Non-candidates for Preoperative Systemic Therapy

- Patients with extensive in situ disease when extent of invasive carcinoma is not well-defined
- Patients with a poorly delineated extent of tumor
- Patients whose tumors are not palpable or clinically assessable

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
PRINCIPLES OF PREOPERATIVE SYSTEMIC THERAPY

- Randomized trials of chemotherapy demonstrate similar long-term outcomes when patients are given the same treatment preoperatively compared with postoperatively.\(^1\)
- Pathologic complete response (pCR) to preoperative systemic therapy is associated with an extremely favorable disease-free and overall survival, particularly in situations in which all treatment is given preoperatively. The correlation between pathologic response and long-term outcome is strongest for TNBC, somewhat less so for HER2-positive disease, and least for ER-positive disease.\(^2,3\)
- A number of chemotherapy regimens have activity in the preoperative setting. In general, those chemotherapy regimens recommended in the adjuvant setting may be considered in the preoperative setting. See Preoperative/Adjuvant Therapy Regimens (BINV-L).
- Preoperative endocrine therapy alone may be considered for patients with ER-positive disease based on comorbidities or low-risk luminal biology.
- Patients with HER2-positive tumors should be treated with preoperative systemic therapy incorporating trastuzumab.\(^a\) A pertuzumab-containing regimen may be administered preoperatively to patients with greater than or equal to T2 or greater than or equal to N1, HER2-positive early-stage breast cancer. See Preoperative/Adjuvant Therapy Regimens (BINV-L).
- Some studies suggest an increased risk of locoregional recurrence following use of preoperative chemotherapy.\(^4\) The trials analyzed used chemotherapy regimens that are no longer standard, did not include targeted therapies, and did not use modern imaging techniques, and some used non-standard locoregional management. Care should be taken to follow the procedures outlined in BINV-12 and BINV-14 to assure appropriate locoregional management. Not all patients are appropriate candidates for preoperative systemic therapy. Accurate clinical staging at baseline prior to initiation of preoperative systemic therapy is critical. See Potentially Operable Disease: Breast and Axillary Evaluation Prior to Preoperative Systemic Therapy (BINV-12).
- Tumor response should be routinely assessed by clinical exam and imaging studies (see footnote xx on BINV-13) during delivery of preoperative therapy. It is preferred that the complete standard regimen should be given prior to surgery. If all intended treatment was not completed prior to surgery, additional chemotherapy to complete the regimen may be given after surgery. Patients with operable breast cancer experiencing progression of disease during preoperative systemic therapy may be given an alternate systemic therapy or taken to surgery. Locoregional therapy principles should be applied in the same manner as in patients treated with adjuvant systemic therapy.

\(^a\) An FDA-approved biosimilar is an appropriate substitute for trastuzumab.

Gene expression assays provide prognostic and therapy-predictive information that complements T,N,M and biomarker information. Use of these assays is not required for staging. The 21-gene assay (Oncotype Dx) is preferred by the NCCN Breast Cancer Panel for node-negative breast cancer. Other prognostic gene expression assays can provide additional prognostic information in patients with 1–3 positive lymph nodes but are unknown if predictive of chemotherapy benefit in 1–3 positive lymph nodes.

See Special Consideration for Breast Cancer in Men (BINV-J).

| **50-gene (PAM 50)**           |                 | For patients with T1 and T2 hormone receptor-positive, HER2-negative, lymph node-negative tumors, a risk of recurrence score in the low range, regardless of T size, places the tumor into the same prognostic category as T1a–T1b,N0,M0.  
| Node negative: Low (0–40)     |                 | In patients with hormone receptor-positive, HER2-negative, 1–3 positive lymph nodes with low risk of recurrence score, treated with endocrine therapy alone, the distant recurrence risk was less than 3.5% at 10 years and no distant recurrence was seen at 10 years in the TransATAC study in a similar group.  
| Node negative: Intermediate (41–60) |                 |  
| Node negative: High (61–100)   |                 |  
| Node positive: Low (0–40)     |                 |  
| Node positive: High (41–100)   |                 |  
| **12-gene (EndoPredict)**      |                 | For patients with T1 and T2 hormone receptor-positive, HER2-negative, and lymph node-negative tumors, a 12-gene low-risk score, regardless of T size, places the tumor into the same prognostic category as T1a–T1b,N0,M0. In ABCSG 6/8, patients in the low-risk group had risk of distant recurrence of 4% at 10 years and in the TransATAC study, patients with 1–3 positive nodes in the low-risk group had a 5.6% risk of distant recurrence at 10 years. The risk score is predictive of chemo-benefit based on a prospective analysis of 3,746 archived, HR-positive, HER2-negative, T1–T3 tumors from chemo-endocrine and endocrine-only cohorts, that included women with lymph node-negative and lymph node-positive disease.  
| Low (<3.33)                    |                 |  
| High (>3.33)                   |                 |  
| **Breast Cancer Index (BCI)**  |                 | For patients with T1 and T2 hormone receptor-positive, HER2-negative, and lymph node-negative tumors, a BCI in the low-risk range, regardless of T size, places the tumor into the same prognostic category as T1a–T1b, N0,M0. Results of a secondary analysis of the aTTom trial demonstrated that in patients with hormone-receptor positive, node-positive breast cancer, patients with a high BCI (HOXB13/IL17BR) (H/I) derived significant benefit from extending tamoxifen therapy to 10 years vs. 5 years. In contrast, BCI (H/I) low patients derived no benefit from extended adjuvant therapy.  
| Low risk of late occurrence (0–5) |                 |  
| High risk of late occurrence (5.1–10) |                 |  |

Note: All recommendations are category 2A unless otherwise indicated.  
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

DEFINITION OF MENOPAUSE

Clinical trials in breast cancer have utilized a variety of definitions of menopause. Menopause is generally the permanent cessation of menses, and as the term is utilized in breast cancer management includes a profound and permanent decrease in ovarian estrogen synthesis. Reasonable criteria for determining menopause include any of the following:

- Prior bilateral oophorectomy
- Age ≥60 y
- Age <60 y and amenorrheic for 12 or more months in the absence of chemotherapy, tamoxifen, toremifene, or ovarian suppression and follicle-stimulating hormone (FSH) and estradiol in the postmenopausal range
- If taking tamoxifen or toremifene, and age <60 y, then FSH and plasma estradiol level in postmenopausal ranges

It is not possible to assign menopausal status to women who are receiving a luteinizing hormone-releasing hormone (LHRH) agonist or antagonist. In women premenopausal at the beginning of adjuvant chemotherapy, amenorrhea is not a reliable indicator of menopausal status as ovarian function may still be intact or resume despite anovulation/amenorrhea after chemotherapy. For these women with therapy-induced amenorrhea, oophorectomy or serial measurement of FSH and/or estradiol are needed to ensure postmenopausal status if the use of aromatase inhibitors is considered as a component of endocrine therapy.
### Systemic Therapy for ER- and/or PR-Positive Recurrent or Stage IV (M1) Disease

#### HER2-Negative and Postmenopausal or Premenopausal Receiving Ovarian Ablation or Suppression

#### Useful in Certain Circumstances\(^c\)

- Megestrol acetate
- Fluoxymesterone
- Ethinyl estradiol
- Abemaciclib\(^a,d\)

\(^a\) If there is disease progression while on CDK4/6 inhibitor therapy, there are limited data to support an additional line of therapy with another CDK4/6-containing regimen. If there is disease progression while on a everolimus-containing regimen, there are no data to support an additional line of therapy with another everolimus regimen.

\(^b\) A single study (S0226) in women with hormone receptor-positive breast cancer and no prior chemotherapy, biological therapy, or endocrine therapy for metastatic disease demonstrated that the addition of fulvestrant to anastrozole resulted in prolongation of time to progression and overall survival. Subset analysis suggested that patients without prior adjuvant tamoxifen and more than 10 years since diagnosis experienced the greatest benefit. Two studies with similar design (FACT and SOFEA) demonstrated no advantage in time to progression with the addition of fulvestrant to anastrozole.

\(^c\) See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R).

\(^d\) Indicated after progression on prior endocrine therapy and prior chemotherapy in the metastatic setting.

\(^e\) A combination of exemestane with everolimus can be considered for patients who meet the eligibility criteria for BOLERO-2 (progressed within 12 mo or on non-steroidal aromatase inhibitor).

\(^f\) An FDA-approved biosimilar is an appropriate substitute for trastuzumab.

\(^g\) Trastuzumab and hyaluronidase-oysk injection for subcutaneous use may be substituted for trastuzumab. It has different dosage and administration instructions compared to intravenous trastuzumab. Do not substitute trastuzumab and hyaluronidase-oysk for or with ado-trastuzumab emtansine or fam-trastuzumab deruxtecan-nxki.

\(^h\) If treatment was initiated with chemotherapy and trastuzumab + pertuzumab, and the chemotherapy was stopped, endocrine therapy may be added to the trastuzumab + pertuzumab.
### HER2-Negative

- For germline BRCA1/2 mutations\(^d\) see additional targeted therapy options (BINV-R)\(^e\)
- Platinum (for TNBC and germline BRCA1/2 mutation)\(^d\)
  ‣ Carboplatin
  ‣ Cisplatin
- For PD-L1–positive TNBC see additional targeted therapy options (BINV-R)\(^e\)

\(^a\) Albumin-bound paclitaxel may be substituted for paclitaxel or docetaxel due to medical necessity (ie, hypersensitivity reaction). If substituted for weekly paclitaxel or docetaxel, then the weekly dose of nab-paclitaxel should not exceed 125 mg/m².

\(^b\) Consider scalp cooling to reduce incidence of chemotherapy-induced alopecia for patients receiving chemotherapy. Results may be less effective with anthracycline-containing regimens.

\(^c\) For treatment of brain metastases, see NCCN Guidelines for Central Nervous System Cancers.

\(^d\) Assess for germline BRCA1/2 mutations in all patients with recurrent or metastatic breast cancer to identify candidates for PARP inhibitor therapy.

\(^e\) See Additional Targeted Therapies and Associated Biomarker Testing for Recurrent or Stage IV (M1) Disease (BINV-R).

\(^f\) Sequential single agents are preferred, but chemotherapy combinations may be used in select patients with high tumor burden, rapidly progressing disease, and visceral crisis.

\(^g\) For adult patients with metastatic TNBC who received at least two prior therapies for metastatic disease.

\(^h\) Randomized clinical trials in metastatic breast cancer document that the addition of bevacizumab to some first- or second-line chemotherapy agents modestly improves time to progression and response rates but does not improve overall survival. The time-to-progression impact may vary among cytotoxic agents and appears greatest with bevacizumab in combination with weekly paclitaxel.

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
HER2-Negative - Preferred Regimens:
- Anthracyclines:
  - Doxorubicin 60–75 mg/m² IV day 1; cycled every 21 days.¹
  - Doxorubicin 20 mg/m² IV day 1 weekly²
  - Liposomal doxorubicin³ 50 mg/m² IV day 1; cycled every 28 days.
- Taxanes:
  - Paclitaxel 175 mg/m² IV day 1; cycled every 21 days.⁴
  - Paclitaxel 80 mg/m² IV day 1 weekly⁵
- Antimetabolites:
  - Capecitabine⁶ 1000–1250 mg/m² PO twice daily days 1–14; cycled every 21 days.
  - Gemcitabine⁷ 800–1200 mg/m² IV days 1, 8, and 15; cycled every 28 days.
- Microtubule inhibitors:
  - Vinorelbine⁸,⁹,¹⁰
    - 25 mg/m² IV day 1 weekly; or
    - 20–35 mg/m² IV days 1 and 8; cycled every 21 days; or
    - 25–30 mg/m² IV days 1, 8, and 15; cycled every 28 days.
  - Eribulin³ 1.4 mg/m² IV days 1 and 8; cycled every 21 days.
- Platinum (for TNBC and germline BRCA1/2 mutation)
  - Carboplatin¹² AUC 6 IV on day 1
    ◊ Cycled every 21–28 days.
  - Cisplatin¹³ 75 mg/m² IV on day 1
    ◊ Cycled every 21 days.

HER2-Negative - Other Regimens:
- Anthracyclines:
  - Cyclophosphamide¹⁵
    - 50 mg PO daily on days 1–21
    ◊ Cycled every 28 days.
- Docetaxel¹⁶,¹⁷
  - 60–100 mg/m² IV day 1
  ◊ Cycled every 21 days.
- Docetaxel¹⁸
  - 35 mg/m² IV weekly for 6 wks followed by a 2-week rest, then repeat.
- Albumin-bound paclitaxel¹⁹,²⁰
  - 100 mg/m² or 125 mg/m² IV days 1, 8, and 15
  ◊ Cycled every 28 days.
- Albumin-bound paclitaxel¹⁹
  - 260 mg/m² IV
  ◊ Cycled every 21 days.
- Epirubicin²¹
  - 60–90 mg/m² IV day 1
  ◊ Cycled every 21 days.
- Ixabepilone²²
  - 40 mg/m² IV day 1
  ◊ Cycled every 21 days.
- Sacituzumab govitecan-hziy (for TNBC)²³
  - 10 mg/kg IV on days 1 and 8
  ◊ Cycled every 21 days

HER2-Negative - Useful in Certain Circumstances:
- AC²⁴
  - Doxorubicin 60 mg/m² IV day 1
  ◊ Cycled every 21 days.
- EC²⁵
  - Epirubicin 75 mg/m² IV day 1
  ◊ Cycled every 21 days.
- CMF²⁶
  - Cyclophosphamide 100 mg/m² PO days 1–14
  - Methotrexate 40 mg/m² IV days 1 and 8
  ◊ Cycled every 28 days.
- Docetaxel/capecitabine²⁷
  - Docetaxel 75 mg/m² IV day 1
  - Capecitabine 950 mg/m² PO twice daily days 1–14
  ◊ Cycled every 21 days.
- GT²⁸
  - Paclitaxel 175 mg/m² IV day 1
  ◊ Cycled every 21 days.
- Gemcitabine/carboplatin²⁹
  - Gemcitabine 1000 mg/m² on days 1 and 8
  ◊ Cycled every 21 days.
- Paclitaxel plus bevacizumab³⁰
  - Paclitaxel 90 mg/m² IV days 1, 8, and 15
  - Bevacizumab 10 mg/kg IV days 1 and 15
  ◊ Cycled every 28 days.
- Carboplatin/albun-bound paclitaxel³¹
  - Carboplatin AUC 2 IV on days 1 and 8
  - Albumin-bound paclitaxel 125 mg/m² IV on days 1 and 8
  ◊ Cycled every 21 days.
- Carboplatin/paclitaxel³²,³³
  - Paclitaxel 175–200 mg/m² IV day 1
  ◊ Cycled every 21 days.
- Carboplatin AUC 6 IV day 1
  ◊ Cycled every 21 days.
- Paclitaxel 100 mg/m² IV days 1, 8, and 15
  ◊ Cycled every 28 days.

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
HER2-Positive - Preferred regimens:1,3,5

- Pertuzumab + trastuzumab + docetaxel34
  - Pertuzumab 840 mg IV day 1 followed by 420 mg IV
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days
  - Docetaxel 75–100 mg/m² IV day 1
    ◊ Cycled every 21 days.

- Pertuzumab + trastuzumab + paclitaxel35
  - Pertuzumab 840 mg IV day 1 followed by 420 mg IV
    ◊ Cycled every 21 days.
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days.36
  - Paclitaxel 80 mg/m² IV day 1 weekly.35 or
  - Paclitaxel 175 mg/m² day 1
    ◊ Cycled every 21 days.

HER2-Positive - Other recommended regimens:1,5

- Tucatinib + trastuzumab + capecitabine37
  - Tucatinib 300 mg orally twice daily on days 1-21
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days
  - Capecitabine 1000mg/m² orally twice daily on days 1-14
    ◊ Cycled every 21 days.

- Ado-trastuzumab emtansine (T-DM1)38
  - 3.6 mg/kg IV day 1
    ◊ Cycled every 21 days.

- Fam-trastuzumab deruxtecan-nxki39
  - 5.4 mg/kg IV day 1
    ◊ Cycled every 21 days.

- Paclitaxel/carboplatin + trastuzumab40
  - Carboplatin AUC 6 IV day 1
    ◊ Cycled every 21 days.
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days.36

- Weekly paclitaxel/carboplatin + trastuzumab41
  - Paclitaxel 80 mg/m² IV day 1 followed by 2 mg/kg IV weekly
    ◊ Cycled every 28 days.
  - Trastuzumab 4 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days.36

- Trastuzumab + paclitaxel42,43
  - Paclitaxel 175 mg/m² IV day 1 cycled every 21 days42 or
  - Paclitaxel 80–90 mg/m² IV day 1 weekly.43
  - Trastuzumab 4 mg/kg IV day 1 followed by 6 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days.36

- Trastuzumab + docetaxel44,45
  - Docetaxel 80–100 mg/m² IV day 1 cycled every 21 days44 or
  - Docetaxel 35 mg/m² IV day 1, 8, and 15 weekly.45
  - Trastuzumab 4 mg/kg IV day 1 followed by 6 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days.36

An FDA-approved biosimilar is an appropriate substitute for trastuzumab.
Trastuzumab and hyaluronidase-oysk injection for subcutaneous use may be substituted for trastuzumab. It has different dosage and administration instructions compared to intravenous trastuzumab. Do not substitute trastuzumab and hyaluronidase-oysk for or with ado-trastuzumab emtansine or fam-trastuzumab deruxtecan-nxki.
Pertuzumab, trastuzumab, and hyaluronidase-zzxf injection for subcutaneous use may be substituted anywhere that the combination of intravenous pertuzumab and intravenous trastuzumab are given as part of systemic therapy. Pertuzumab, trastuzumab, and hyaluronidase-zzxf injection for subcutaneous use has different dosing and administration instructions compared to the intravenous products.

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
HER2-Positive - Other recommended regimens (continued):\(^{ij}\)

- **Trastuzumab + vinorelbine\(^{46-48}\)**
  - Vinorelbine
    - \(25 \text{ mg/m}^2\) IV day 1 weekly; or
    - \(20–35 \text{ mg/m}^2\) IV days 1 and 8; cycled every 21 days; or
    - \(25–30 \text{ mg/m}^2\) IV days 1, 8, and 15; cycled every 28 days
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days\(^{36}\)

- **Trastuzumab + capecitabine\(^{49}\)**
  - Capecitabine 1000–1250 mg/m\(^2\) PO twice daily days 1–14 cycled every 21 days
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly\(^{42,50}\)
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days\(^{36}\)

- **Lapatinib + capecitabine\(^{51}\)**
  - Lapatinib 1250 mg PO daily days 1–21
  - Capecitabine 1000 mg/m\(^2\) PO twice daily days 1–14
    ◊ Cycled every 21 days.

- **Trastuzumab + capecitabine\(^{52}\)**
  - Capecitabine 1000–1250 mg/m\(^2\) PO twice daily days 1–14
    ◊ Cycled every 21 days.
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly\(^{42,50}\)
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days\(^{36}\)

- **Trastuzumab + lapatinib\(^{53}\)**
  - Lapatinib 1000 mg PO daily
  - Trastuzumab 4 mg/kg IV day 1 followed by 2 mg/kg IV weekly
    or
  - Trastuzumab 8 mg/kg IV day 1 followed by 6 mg/kg IV day 1 every 21 days\(^{36}\)

- **Neratinib + capecitabine\(^{54}\)**
  - Neratinib 240 mg PO daily on days 1–21
  - Capecitabine 750 mg/m\(^2\) PO twice daily on days 1–14
    ◊ Cycled every 21 days.

\(^{ij}\) An FDA-approved biosimilar is an appropriate substitute for trastuzumab.

\(^i\) Trastuzumab and hyaluronidase-oysk injection for subcutaneous use may be substituted for trastuzumab. It has different dosage and administration instructions compared to intravenous trastuzumab. Do not substitute trastuzumab and hyaluronidase-oysk for or with ado-trastuzumab emtansine or fam-trastuzumab deruxtecan-nxki.

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

**Note:** All recommendations are category 2A unless otherwise indicated.

\(^a\) Assess for germline BRCA1/2 mutations in all patients with recurrent or metastatic breast cancer to identify candidates for PARP inhibitor therapy. While olaparib and talazoparib are FDA indicated in HER2-negative disease, the panel supports use in any breast cancer subtype associated with a germline BRCA1 or BRCA2 mutation.

\(^b\) For HR-positive/HER2-negative breast cancer, assess for PIK3CA mutations with tumor or liquid biopsy to identify candidates for alpelisib plus fulvestrant. PIK3CA mutation testing can be done on tumor tissue or ctDNA in peripheral blood (liquid biopsy). If liquid biopsy is negative, tumor tissue testing is recommended.

\(^c\) For TNBC, assess PD-L1 expression biomarker status on tumor-infiltrating immune cells to identify candidates for atezolizumab plus albumin-bound paclitaxel.

\(^d\) The safety of alpelisib in patients with Type 1 or uncontrolled Type 2 diabetes has not been established.

\(^e\) Larotrectinib and entrectinib are indicated for the treatment of solid tumors that have an NTRK gene fusion without a known acquired resistance mutation and have no satisfactory alternative treatments or that have progressed following treatment.

\(^f\) Pembrolizumab is indicated for the treatment of patients with unresectable or metastatic, microsatellite instability-high (MSI-H) or mismatch repair deficient (dMMR) solid tumors that have progressed following prior treatment and who have no satisfactory alternative treatment options.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
ADDITIONAL TARGETED THERAPIES AND ASSOCIATED BIOMARKER TESTING FOR RECURRENT OR STAGE IV (M1) DISEASE

Dose Schedules for Additional Targeted Therapies

Preferred Regimens:

- **Olaparib**
  - 300 mg PO twice daily
  - Cycled every 28 days

- **Talazoparib**
  - 1 mg PO daily
  - Cycled every 28 days

- **Alpelisib + fulvestrant**
  - Alpelisib 300 mg PO daily on days 1–28; fulvestrant 500 mg IM on days 1 and 15
    - ◊ 28-day cycle for 1 cycle
  - Followed by alpelisib 300 mg PO daily on days 1–28; fulvestrant 500 mg IM on day 1
    - ◊ Cycled every 28 days until disease progression or unacceptable toxicity

- **Atezolizumab + albumin-bound paclitaxel**
  - Atezolizumab 840 mg IV on days 1 and 15
  - Albumin-bound paclitaxel 100 mg/m² IV on days 1, 8, and 15
  - Cycled every 28 days

Useful in Certain Circumstances:

- **Larotrectinib**
  - 100 mg PO twice daily on days 1–28
  - Cycled every 28 days until disease progression or unacceptable toxicity

- **Entrectinib**
  - 600 mg PO daily on days 1–28
  - Cycled every 28 days until disease progression or unacceptable toxicity

- **Pembrolizumab**
  - 200 mg IV on day 1, every 21-days until disease progression or unacceptable toxicity
    or
  - 400 mg IV on day 1, every 6 weeks until disease progression or unacceptable toxicity, or up to 24 months

Note: There is also a capsule formulation available. However, do not substitute the capsules for the tablets on a mg-per-mg basis due to differences in dosing and bioavailability.

The selection, dosing, and administration of anti-cancer agents and the management of associated toxicities are complex. Modifications of drug dose and schedule and initiation of supportive care interventions are often necessary because of expected toxicities and individual patient variability, prior treatment, and comorbidity. The optimal delivery of anti-cancer agents therefore requires a health care delivery team experienced in the use of anti-cancer agents and the management of associated toxicities in patients with cancer.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF MONITORING METASTATIC DISEASE

Monitoring of patient symptoms and cancer burden during treatment of metastatic breast cancer is important to determine whether the treatment is providing benefit and that the patient does not have toxicity from an ineffective therapy.

Components of Monitoring
Monitoring includes periodic assessment of varied combinations of symptoms, physical examination, routine laboratory tests, imaging studies, and blood biomarkers where appropriate. Results of monitoring are classified as response/continued response to treatment, stable disease, uncertainty regarding disease status, or progression of disease. The clinician typically must assess and balance multiple different forms of information to make a determination regarding whether disease is being controlled and the toxicity of treatment is acceptable. Sometimes, this information may be contradictory. Clinicians should take into account patient preferences through a shared decision-making process.

Definition of Disease Progression
Unequivocal evidence of progression of disease by one or more of these factors is required to establish progression of disease, either because of ineffective therapy or acquired resistance of disease to an applied therapy. Progression of disease may be identified through evidence of growth or worsening of disease at previously known sites of disease and/or of the occurrence of new sites of metastatic disease.

• Findings concerning for progression of disease include:
  › Worsening symptoms such as pain or dyspnea
  › Evidence of worsening or new disease on physical examination
  › Declining performance status
  › Unexplained weight loss
  › Increasing alkaline phosphatase, alanine aminotransferase (ALT), aspartate transaminase (AST), or bilirubin
  › Hypercalcemia
  › New radiographic abnormality or increase in the size of pre-existing radiographic abnormality
  › New areas of abnormality on functional imaging (eg, bone scan, PET/CT)
  › Increasing tumor markers (eg, carcinoembryonic antigen [CEA], CA 15-3, CA 27.29)\(^a\)

\(^a\) Rising tumor markers (eg, CEA, CA 15-3, CA 27.29) are concerning for tumor progression, but may also be seen in the setting of responding disease. An isolated increase in tumor markers should rarely be used to declare progression of disease. Changes in bone lesions are often difficult to assess on plain or cross-sectional radiology or on bone scan. For these reasons, patient symptoms and serum tumor markers may be more helpful in patients with bone-dominant metastatic disease.
PRINCIPLES OF MONITORING METASTATIC DISEASE

Use of Objective Criteria for Response/Stability/Progression

• The most accurate assessments of disease activity typically occur when previously abnormal studies are repeated on a serial and regular basis. Generally, the same method of assessment should be used over time (e.g., an abnormality found on chest CT should generally be monitored with repeat chest CT).

• Some non-clinically important variation in measurement of abnormalities by all serial studies is common and expected. Therefore, the use of objective and widely accepted criteria for response, stability, and progression of disease are encouraged. Such systems include the Response Evaluation Criteria In Solid Tumors (RECIST) guidelines (Eisenhauer EA, Therasse P, Bogaerts J, et al. New response evaluation criteria in solid tumours: revised RECIST guideline (version 1.1). Eur J Cancer 2009;45:228-247) and the WHO criteria (Miller AB, Hoogstraten B, Staquet M, Winkler A. Reporting results of cancer treatment. Cancer 1981;47:207-214).

• Studies of functional imaging, such as radionuclide bone scans and PET imaging, are particularly challenging when used to assess response. In the case of bone scans, responding disease may result in a flare or increased activity on the scan that may be misinterpreted as disease progression, especially on the first follow-up bone scan after initiating a new therapy. PET imaging is challenging because of the absence of a reproducible, validated, and widely accepted set of standards for disease activity assessment.
**PRINCIPLES OF MONITORING METASTATIC DISEASE**

**Frequency of Monitoring**
The optimal frequency of repeat testing is uncertain, and is primarily based on the monitoring strategies utilized in breast cancer clinical trials. The frequency of monitoring must balance the need to detect progressive disease, avoid unnecessary toxicity of any ineffective therapy, resource utilization, and determine cost. The following table is to provide guidance, and should be modified for the individual patient based on sites of disease, biology of disease, and treatment regimen. Reassessment of disease activity should be performed in patients with new or worsening signs or symptoms of disease, regardless of the time interval from previous studies.

**Suggested Intervals of Follow-up for Patients with Metastatic Disease**

## Clinical Presentation

Clinical suspicion for phyllodes tumor:
- Palpable mass
- Rapid growth
- Large size (>3 cm)
- Imaging with ultrasound suggestive of fibroadenoma except for size and/or history of growth

## Workup

- History and physical exam
- Ultrasound
- Mammogram for women ≥30 y

## Findings

- **Fibroadenoma**
  - Observe

- **Excisional biopsy**
  - **Phyllodes tumor includes benign, borderline, and malignant**
    - **Wide excision**
      - **Without axillary staging**
        - Clinical follow-up for 3 y

- **Invasive or in situ cancer**
  - See appropriate guidelines

- **Core needle biopsy**
  - **Phyllodes tumor includes benign, borderline, and malignant**
    - **Wide excision**
      - **Without axillary staging**
        - Clinical follow-up for 3 y

- **Fibroadenoma or indeterminate**
  - See findings above

## Treatment

- **Excisional biopsy**
  - **Phyllodes tumor includes benign, borderline, and malignant**
    - **Wide excision**
      - **Without axillary staging**
        - Clinical follow-up for 3 y

- **Invasive or in situ cancer**
  - See appropriate guidelines

## Surveillance

- Clinical follow-up for 3 y

---

### Notes

- Excisional biopsy includes complete mass removal, but without the intent of obtaining surgical margins.
- FNA or core biopsy may not distinguish a fibroadenoma from a phyllodes tumor in some cases. The sensitivity of core biopsy for the diagnosis of phyllodes tumor is greater than that of FNA biopsy, but neither core biopsy nor FNA biopsy can always differentiate phyllodes tumors from fibroadenomas. In cases with clinical suspicion for phyllodes tumor, excision of the lesion may be needed for definitive pathologic classification.
- For malignant or borderline disease, wide excision means excision with the intention of obtaining surgical margins ≥1 cm. Narrow surgical margins are associated with heightened local recurrence risk, but are not an absolute indication for mastectomy when partial mastectomy fails to achieve margin width ≥1 cm.
- There are no prospective randomized data supporting the use of radiation treatment with phyllodes tumors. However, in the setting where additional recurrence would create significant morbidity (eg, chest wall recurrence following mastectomy), RT may be considered following the same principles that are applied to the treatment of soft tissue sarcoma.

---

**Note:** All recommendations are category 2A unless otherwise indicated. Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**NCCN Guidelines Version 5.2020**

**Paget's Disease**

### WORKUP

- **Examination or imaging positive for breast lesion**
  - Core biopsy of breast lesion and full-thickness skin biopsy of involved NAC

- **Examination and imaging negative for breast lesion**
  - Full-thickness skin biopsy of involved NAC
  - NAC biopsy positive for Paget's
  - NAC biopsy negative for Paget's

### TREATMENT

- **Breast and NAC biopsy negative**
  - Clinical follow-up
  - Re-biopsy if not healing

- **Breast DCIS and NAC Paget's**
  - See NCCN Guidelines for Noninvasive Breast Cancer for DCIS (DCIS-1)

- **Breast invasive cancer and NAC Paget's**
  - See NCCN Guidelines for Invasive Breast Cancer (BINV-1)
  - Central lumpectomy including NAC with WBRT or Total mastectomy ± sentinel node biopsy with or without breast reconstruction or Central lumpectomy including NAC ± sentinel node biopsy without RT (category 2B)

- **Breast negative for cancer and positive NAC Paget's**
  - Consider breast MRI\(^b\) and tissue sampling

- **NAC biopsy positive for Paget's**
  - Clinical follow-up
  - Re-biopsy if not healing

- **NAC biopsy negative for Paget's**
  - See NCCN Guidelines for Noninvasive Breast Cancer for DCIS (DCIS-1)

- **Appropriate systemic adjuvant therapy as clinically indicated**

---

\(^b\)See Principles of Dedicated Breast MRI Testing (BINV-B).

\(^c\)Mastectomy is always an option with any manifestation of Paget's disease (See Discussion).

---

**Note:** All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
CT scans and nuclear imaging are contraindicated during pregnancy.

Considerations and selection of optimal local therapy and systemic therapy are similar to that recommended in non-pregnancy-associated breast cancer; see other sections of this guideline. However, the selection and timing of chemotherapy, endocrine therapy, and RT is different in the pregnant versus non-pregnant patient (See Discussion). Chemotherapy should not be administered during the first trimester of pregnancy, and RT should not be administered during any trimester of pregnancy. Coordination is recommended between the oncology and obstetrics teams to plan the optimal timing of systemic therapy administration during pregnancy. Most experience with chemotherapy during pregnancy for breast cancer is from regimens that utilize various combinations of doxorubicin, cyclophosphamide, and fluorouracil. Considerations for postpartum chemotherapy are the same as for non–pregnancy-associated breast cancer.

Use of blue dye is contraindicated in pregnancy; radiolabeled sulfur colloid appears to be safe for sentinel node biopsy in pregnancy. See Surgical Axillary Staging (BINV-D).

There are insufficient safety data to recommend general use of taxanes during pregnancy. The use of anti-HER2 therapy is contraindicated during pregnancy.

If late 1st trimester, may consider preoperative chemotherapy in the 2nd trimester.
Clinical pathologic diagnosis of IBC

**WORKUP**

- History and physical exam by multidisciplinary team and obtain medical photography
- CBC
- Comprehensive metabolic panel, including liver function tests and alkaline phosphatase
- Pathology review
- Determination of tumor ER/PR status and HER2 status
- Bilateral diagnostic mammogram, ultrasound as necessary
- Breast MRI (optional)
- Bone scan or sodium fluoride PET/CT (category 2B)
- Chest/abdominal/pelvic diagnostic CT with contrast (category 2B)
- Genetic counseling if patient is at risk for hereditary breast cancer
- FDG PET/CT (optional)

**Response**

- Preoperative systemic therapy, \( ^i \) anthracycline + taxane (preferred). \( ^i \) If tumor HER2-positive, HER2-targeted therapy

---

\( ^a \) IBC is a clinical syndrome in women with invasive breast cancer that is characterized by erythema and edema (peau d'orange) of a third or more of the skin of the breast. The differential diagnosis includes cellulitis of the breast or mastitis. Pathologically, a tumor is typically present in the dermal lymphatics of the involved skin, but dermal lymphatic involvement is neither required, nor sufficient by itself for a diagnosis of IBC.

\( ^c \) See Principles of Biomarker Testing (BINV-A).

\( ^d \) See Fertility and Birth Control (BINV-C).

\( ^e \) If FDG PET/CT is performed and clearly indicates bone metastasis on both the PET and CT component, bone scan or sodium fluoride PET/CT may not be needed.

\( ^f \) For risk criteria, see NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

\( ^g \) FDG PET/CT can be performed at the same time as diagnostic CT. FDG PET/CT is most helpful in situations where standard staging studies are equivocal or suspicious, especially in the setting of locally advanced or metastatic disease.

\( ^h \) FDG PET/CT may also be helpful in identifying unsuspected regional nodal disease and/or distant metastases in locally advanced breast cancer when used in addition to standard staging studies.

\( ^i \) See Preoperative/Adjuvant Therapy Regimens (BINV-L).

\( ^j \) A pertuzumab-containing regimen may be administered preoperatively to patients with HER2-positive IBC.

\( ^k \) The accurate assessment of in-breast tumor or regional lymph node response to preoperative systemic therapy is difficult, and should include physical examination and performance of imaging studies (mammogram and/or breast MRI) that were abnormal at the time of initial tumor staging. Selection of imaging methods prior to surgery should be determined by the multidisciplinary team.

---

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
**TREATMENT**

**Response**
- Total mastectomy + level I/II axillary dissection + RT to chest wall, infraclavicular region, supraclavicular area, internal mammary nodes, and any part of the axillary bed at risk ± delayed breast reconstruction

**Response**
- Complete planned chemotherapy regimen course if not completed preoperatively plus endocrine treatment if ER-positive and/or PR-positive (sequential chemotherapy followed by endocrine therapy).
- Complete up to one year of HER2-targeted therapy if HER2-positive (category 1). May be administered concurrently with RTP and with endocrine therapy if indicated.

**No response**
- Consider additional systemic chemotherapy and/or preoperative radiation

**No response**
- Individualized treatment

### Footnotes:
- k The accurate assessment of in-breast tumor or regional lymph node response to preoperative systemic therapy is difficult, and should include physical examination and performance of imaging studies (mammogram and/or breast MRI) that were abnormal at the time of initial tumor staging. Selection of imaging methods prior to surgery should be determined by the multidisciplinary team.
- l Patients with recurrent IBC should be treated according to the guideline for recurrence/stage IV (M1) disease (BINV-18).
- m See Principles of Breast Reconstruction Following Surgery (BINV-H).
- n See Systemic Therapy Regimens for Recurrent or Stage IV (M1) Disease (BINV-Q).
- o See Adjuvant Endocrine Therapy (BINV-K).
- p See Principles of Radiation Therapy (BINV-I).

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.
Primary Tumor (T) The T category of the primary tumor is defined by the same criteria regardless of whether it is based on clinical or pathological criteria, or both. The T category is based primarily on the size of the invasive component of the cancer. The maximum size of a tumor focus is used as an estimate of disease volume. The largest contiguous dimension of a tumor focus is used, and small satellite foci of noncontiguous tumor are not added to the size. The cellular fibrous reaction to invasive tumor cells is generally included in the measurement of a tumor prior to treatment; however, the dense fibrosis observed following neoadjuvant treatment is generally not included in the pathological measurement because its extent may overestimate the residual tumor volume. The clinical size of a primary tumor (T) can be measured based on clinical findings (physical examination and imaging modalities, such as mammography, ultrasound, and MR imaging) and pathological findings (gross and microscopic measurements). Clinical tumor size (cT) should be based on the clinical findings that are judged to be most accurate for a particular case, although it may still be somewhat inaccurate because the extent of some breast cancers is not always apparent with current imaging techniques and because tumors are composed of varying proportions of noninvasive and invasive disease, which these techniques are currently unable to distinguish. Size should be measured to the nearest millimeter. If the tumor size is slightly less than or greater than a cutoff for a given T classification the size should be rounded to the millimeter reading that is closest to the cutoff. For example, a reported size of 4.9 mm is reported as 5 mm, or a size of 2.04 cm is reported as 2.0 cm (20 mm). The exception to this rounding rule is for a breast tumor sized between 1.0 and 1.4 mm. These sizes are rounded up to 2 mm, because rounding down would result in the cancer’s being categorized as microinvasive carcinoma (T1mi) defined as a size of 1.0 mm or less.

Note: (sn) and (f) suffixes should be added to the N category to denote confirmation of metastasis by sentinel node biopsy or fine needle aspiration/core needle biopsy respectively.

*The cNX category is used sparingly in cases where regional lymph nodes have previously been surgically removed or where there is no documentation of physical examination of the axilla.

**cN1mi is rarely used but may be appropriate in cases where sentinel node biopsy is performed before tumor resection, most likely to occur in cases treated with neoadjuvant therapy.
Table 1. Definitions for T, N, M (continued)

Pathologic (pN)

**pN3**
Metastases in 10 or more axillary lymph nodes; 
or in infraclavicular (level III axillary) lymph nodes; 
or positive ipsilateral internal mammary lymph nodes by imaging in the presence of one or more positive level I, II axillary lymph nodes; 
or in more than three axillary lymph nodes and micrometastases or macrometastases by sentinel lymph node biopsy in clinically negative ipsilateral internal mammary lymph nodes; 
or in ipsilateral supraclavicular lymph nodes

**pN3a**
Metastases in 10 or more axillary lymph nodes (at least one tumor deposit larger than 2.0 mm); 
or metastases to the infraclavicular (level III axillary lymph) nodes

**pN3b**
pN1a or pN2a in the presence of cN2b (positive internal mammary nodes by imaging); 
or pN2a in the presence of pN1b

**pN3c**
Metastases in ipsilateral supraclavicular lymph nodes

Note: (sn) and (f) suffixes should be added to the N category to denote confirmation of metastasis by sentinel node biopsy or FNA/core needle biopsy respectively, with NO further resection of nodes

Distant Metastasis (M)

**M0**
No clinical or radiographic evidence of distant metastases*

**cM0(i+)**
No clinical or radiographic evidence of distant metastases in the presence of tumor cells or deposits no larger than 0.2 mm detected microscopically or by molecular techniques in circulating blood, bone marrow, or other nonregional nodal tissue in a patient without symptoms or signs of metastases

**cM1**
Distant metastases detected by clinical and radiographic means

**pM1**
Any histologically proven metastases in distant organs; 
or if in non-regional nodes, metastases greater than 0.2 mm

Table 2. AJCC Anatomic Stage Groups

The Anatomic Stage Group table should only be used in global regions where biomarker tests are not routinely available.

Cancer registries in the U.S. must use the Clinical and Pathological Prognostic Stage Group tables for case reporting.

</table>

Notes:
1. T1 includes T1mi.
2. T0 and T1 tumors with nodal micrometastases (N1mi) are staged as Stage IB.
3. T2, T3, and T4 tumors with nodal micrometastases (N1mi) are staged using the N1 category.
4. M0 includes M0(i+).
5. The designation pM0 is not valid; any M0 is clinical.
6. If a patient presents with M1 disease prior to neoadjuvant systemic therapy, the stage is considered Stage IV and remains Stage IV regardless of response to neoadjuvant therapy.
7. Stage designation may be changed if postsurgical imaging studies reveal the presence of distant metastases, provided the studies are performed within 4 months of diagnosis in the absence of disease progression, and provided the patient has not received neoadjuvant therapy.
8. Staging following neoadjuvant therapy is designated with “yc” or “yp” prefix to the T and N classification. There is no anatomic stage group assigned if there is a complete pathological response (pCR) to neoadjuvant therapy, for example, ypT0ypN0cM0.

Table 2. AJCC Anatomic Stage Groups (continued)

Histologic Grade (G)
All invasive breast carcinomas should be assigned a histologic grade. The Nottingham combined histologic grade (Nottingham modification of the SBR grading system) is recommended and is stipulated for use by the College of American Pathologists (see www.cap.org). The grade for a tumor is determined by assessing morphologic features (tubule formation, nuclear pleomorphism, and calibrated mitotic count), assigning a value from 1 (favorable) to 3 (unfavorable) for each feature, and totaling the scores for all three categories. A combined score of 3–5 points is designated as grade 1; a combined score of 6–7 points is grade 2; a combined score of 8–9 points is grade 3. The use of subjective grading alone is discouraged.

Invasive Cancer (Scarff-Bloom-Richardson [SBR] Grading System, Nottingham Modification)

</tbody>
</table>

Histopathologic Type
The histopathologic types are the following:

In situ Carcinomas
- Ductal carcinoma in situ
- Paget disease

Invasive Carcinomas
- Not otherwise specified (NOS)
- Ductal
- Inflammatory
- Medullary, NOS
- Medullary with lymphoid stroma
- Mucinous
- Papillary (predominantly micropapillary pattern)
- Tubular
- Lobular
- Paget disease and infiltrating
- Undifferentiated
- Squamous cell
- Adenoid cystic
- Secretory
- Cribriform
Table 3. Clinical Prognostic Stage
Clinical Prognostic Stage applies to ALL patients with breast cancer for clinical classification and staging. It uses clinical tumor (T), node (N) and metastases (M) information based on history, physical examination, any imaging performed (not necessary for clinical staging) and relevant biopsies. Genomic profile information is not included in Clinical Prognostic Stage as pathologic information from surgery is necessary to ascertain the prognosis using these tools.

**Notes:**
1. Because N1mi categorization requires evaluation of the entire node, and cannot be assigned on the basis of an FNA or core biopsy, N1mi can only be used with Clinical Prognostic Staging when clinical staging is based on a resected lymph node in the absence of resection of the primary cancer, such as the situation where sentinel node biopsy is performed prior to receipt of neoadjuvant chemotherapy or endocrine therapy.
2. For cases with lymph node involvement with no evidence of primary tumor (e.g. T0 N1, etc.) or with breast ductal carcinoma *in situ* (e.g. Tis N1, etc.), the grade, HER2, ER, and PR information from the tumor in the lymph node should be used for assigning stage group.
3. For cases where HER2 is determined to be “equivocal” by ISH (FISH or CISH) testing under the 2013 ASCO/CAP HER2 testing guidelines, the HER2 “negative” category should be used for staging in the Clinical Prognostic Stage Group.
4. The prognostic value of these Prognostic Stage Groups is based on populations of persons with breast cancer that have been offered and mostly treated with appropriate endocrine and/or systemic chemotherapy (including anti-HER2 therapy).

***N1 includes N1mi. T2, T3, and T4 cancers and N1mi are included for prognostic staging with T2 N1, T3 N1 and T4 N1, respectively.
**Table 4. Pathological Prognostic Stage**

Pathological Prognostic Stage applies to patients with breast cancer treated with surgery as the initial treatment. It includes all information used for clinical staging plus findings at surgery and pathological findings from surgical resection. Pathological Prognostic Stage does not apply to patients treated with systemic or radiation prior to surgical resection (neoadjuvant therapy).

<td>Any</td>
<td>Negative</td>
<td>Positive</td>
<td>Any</td>
<td></td>
</tr>
</tbody>
</table>

Notes:
1. Obtaining genomic profiles is NOT required for assigning Pathological Prognostic Stage. However genomic profiles may be performed for use in determining appropriate treatment. If the OncotypeDx® test is performed in cases with a T1N0M0 or T2N0M0 cancer that is HER2-negative and ER-positive, and the recurrence score is less than 11, the case should be assigned Pathological Prognostic Stage Group IA.
2. If OncotypeDx® is not performed, or if it is performed and the OncotypeDx® score is not available, or is 11 or greater for patients with T1–2 N0 M0 HER2-negative, ER-positive cancer, then the Prognostic Stage Group is assigned based on the anatomic and biomarker categories shown above.
3. OncotypeDx® is the only multigene panel included to classify Pathologic Prognostic Stage because prospective Level I data supports this use for patients with a score less than 11. Future updates to the staging system may include results from other multigene panels to assign cohorts of patients to Prognostic Stage Groups based on the then available evidence. Inclusion or exclusion in this staging table of a genomic profile assay is not an endorsement of any specific assay and should not limit appropriate clinical use of any genomic profile assay based on evidence available at the time of treatment.
### NCCN Categories of Evidence and Consensus

<table>
<thead>
<tr>

Overview

Breast cancer is the most common malignancy in women in the United States and is second only to lung cancer as a cause of cancer death. The American Cancer Society has estimated that 279,100 Americans will be diagnosed with breast cancer and 42,690 will die of disease in the United States in 2020. The therapeutic options for patients with noninvasive or invasive breast cancer are complex and varied. These NCCN Clinical Practice Guidelines for Breast Cancer include up-to-date guidelines for clinical management of patients with carcinoma in situ, invasive breast cancer, Paget's disease, Phyllodes tumor, inflammatory breast cancer, and breast cancer during pregnancy. These guidelines are developed by a multi-disciplinary panel of representatives from NCCN member institutions with breast cancer-focused expertise in the fields of medical oncology, surgical oncology, radiation oncology, pathology, reconstructive surgery, and patient advocacy.

Literature Search Criteria and Guidelines Update Methodology

Prior to the update of this version of the NCCN Guidelines® for Breast Cancer, an electronic search of the PubMed database was performed to obtain key literature in Breast Cancer: Breast Cancer, Breast Neoplasms, DCIS, Inflammatory Breast Cancer OR Phyllodes. The PubMed database was chosen as it remains the most widely used resource for medical literature and indexes peer-reviewed biomedical literature.

The search results were narrowed by selecting studies in humans published in English. Results were confined to the following article types: Clinical Trial, Phase III; Clinical Trial, Phase IV; Guideline; Randomized Controlled Trial; Meta-Analysis; Systematic Reviews; and Validation Studies.

The potential relevance of the PubMed search was examined. The data from key PubMed articles selected by the panel for review during the Guidelines update meeting as well as articles from additional sources deemed as relevant to these Guidelines and discussed by the panel have been included in this version of the Discussion section. Recommendations for which high-level evidence is lacking are based on the panel's review of lower-level evidence and expert opinion. The complete details of the Development and Update of the NCCN Guidelines are available on the NCCN webpage.

Staging

All patients with breast cancer should be assigned a clinical stage of disease, and, if appropriate evaluation is available, a pathologic stage of disease. The routine use of staging allows for efficient identification of local treatment options, assists in identifying systemic treatment options, allows for the comparison of outcome results across institutions and clinical trials, and provides baseline prognostic information.

Effective January 2010, the AJCC implemented a revision of the 7th edition of the AJCC Cancer Staging Manual containing important changes and additions to the TNM staging system for breast cancer. This revision differs from the 2003 edition of the AJCC staging manual by providing more direction relating to the specific methods of clinical and pathologic tumor measurement; recommending that all invasive cancers should be assigned a combined histologic tumor grade using the Elston-Ellis modification of the Scarff-Bloom-Richardson grading system; providing clarification of the classification of isolated tumor cells in axillary lymph node (ALN) staging; subdividing stage I into stage IA and IB based upon the presence or absence of nodal micrometastases (N0 versus N0mi+);
and defining a new category of M0(i+) disease referring to tumor cells microscopically detectable in bone marrow or circulating blood or found incidentally in other tissues not exceeding 0.2 mm in patients who have no signs or symptoms of metastasis. This version of the AJCC staging manual also recommends the collection of biomarkers such as hormone receptor (HR) status (estrogen receptor [ER] and progesterone receptor [PR]) and human epidermal growth factor receptor 2 [HER2] status, although these characteristics do not specifically influence assigned stage of disease.

Pathology Assessment

A central component of the treatment of breast cancer is full knowledge of extent of disease and biologic features. These factors contribute to the determination of the stage of disease, assist in the estimation of the risk that the cancer will recur, and provide information that predicts response to therapy (eg, ER, PR, HER2). These factors are determined by examination of excised tissue and are provided in a written pathology report. Accurate pathology reporting requires communication between the clinician and the pathologist relating to relevant patient history, prior breast biopsies, prior irradiation to the chest, pregnancy status, characteristics of the abnormality biopsied (eg, palpable, mammographically detected microcalcifications), clinical state of lymph nodes, presence of inflammatory change or other skin abnormality, and any prior treatment administered (eg, chemotherapy, radiation therapy). The specimens should be oriented for the pathologist, and specific requests for determination of biomarkers should be stated (eg, ER, PR, and HER2 status). The use of consistent, unambiguous standards for reporting is strongly encouraged. Data from both national and local surveys show that as many as 50% of pathology reports for breast cancer are missing some elements critical to patient management. Significant omissions include failure to orient and report surgical margins and failure to report tumor grade consistently.

The College of American Pathologists (CAP) has developed pathology reporting protocols to promote complete and standardized reporting of malignant specimens. CAP provides a protocol for each disease site that includes cancer case summaries (checklists) along with background documentation. These checklists form the basis for a synoptic, standardized reporting of pathologic findings. The checklists are available without charge through the CAP website at www.cap.org. Consistent, unambiguous, and complete pathology reporting is a cornerstone of quality breast cancer care, and the NCCN Breast Cancer Panel endorses the use of the CAP protocols for reporting the pathologic analysis of all breast cancer specimens.

ER status should be determined for all samples of ductal carcinoma in situ (DCIS), and ER and PR tumor status should be determined for all samples of invasive breast cancer. ER and PR tumor status is normally determined by immunohistochemistry (IHC) testing. Although this method is considered reliable when performed by experienced pathology personnel, there have been several reports indicating that the reliability of ER and PR determinations can vary widely from one laboratory to another. These inter-laboratory differences may be attributable to the diverse methodologies and diverse interpretation schema used to evaluate tumor hormonal status. An NCCN Task Force and a panel of ASCO and CAP members have reviewed this topic and issued recommendations on ER and PR testing in breast cancer. Breast cancers that have at least 1% of cells staining positive for ER should be considered ER-positive.

Principles of HER2 Testing

Along with ER and PR, the determination of HER2 tumor status is recommended for all newly diagnosed invasive breast cancers and for first recurrences of breast cancer whenever possible. The NCCN Breast Cancer Panel endorses CAP accreditation for anatomic pathology
laboratories performing HER2 testing. HER2 status can be assessed by measuring the number of HER2 gene copies using in situ hybridization (ISH) techniques, or by a complementary method in which the quantity of HER2 cell surface receptors is assessed by IHC. Assignment of HER2 status based on mRNA assays or multigene arrays is not recommended. The accuracy of HER2 assays used in clinical practice is a major concern, and results from several studies have shown that false-positive as well as false-negative HER2 test results are common. A joint panel from ASCO and CAP has issued updated HER2 testing guidelines to avoid such false-positive or false-negative results. These updated guidelines have been published in the Archives of Pathology & Laboratory Medicine and ASCO's Journal of Clinical Oncology. The NCCN Panel endorses these updated ASCO/CAP recommendations for quality HER2 testing and has outlined these recommendations in Principles of HER2 Testing in the NCCN Guidelines for Breast Cancer.

HER2 testing should be performed in laboratories accredited by CAP or another equivalent authority to carry out such testing. Further, these laboratories should have standardized HER2 testing procedures in place, as well as programs to periodically evaluate the proficiency of personnel performing HER2 testing. HER2 test reports should also include information on site of tumor, specimen type, histologic type, fixation method and time, block examined, and details on the HER2 testing method(s) used. Clinicians should be familiar with the significance of these criteria when making clinical recommendations for an individual patient.

HER2-Positive Result: Consistent with the ASCO/CAP guidelines, the NCCN Panel considers either IHC or ISH with either a single or dual probe as an acceptable method for making an initial determination of HER2 tumor status. Breast cancer tumors are classified as HER2-positive if they are scored as 3+ by an IHC method defined as uniform membrane staining for HER2 in 10% or more of tumor cells or demonstrate HER2 gene amplification by an ISH method (single probe, average HER2 copy number ≥6.0 signals/cell; dual probe HER2/CEP17 ratio ≥2.0 with an average HER2 copy number ≥4.0 signals/cell; dual probe HER2/chromosome enumeration probe (CEP)17 ratio ≥2.0 with an average HER2 copy number <4.0 signals/cell; and HER2/CEP17 ratio <2.0 with an average HER2 copy number ≥6.0 signals/cell).

High average copy number of HER2 (≥6.0 signals/cell) is considered positive regardless of the HER2/CEP17 ratio. The rationale cited by the joint committee for including rare scenarios such as HER2 positivity when dual probe HER2/CEP17 ratio is greater than or equal to 2.0 and average HER2 copy number is less than 4.0 signals/cell is that the first-generation trials of adjuvant trastuzumab included a small number of patients with a HER2/CEP17 ratio greater than or equal to 2.0 and average HER2 copy number less than 4.0 signals/cell is that the trastuzumab has a favorable safety profile.

Equivocal Result: The NCCN Panel agrees with the ASCO/CAP HER2 committee that results of IHC are equivocal if scored as IHC 2+ “based on circumferential membrane staining that is incomplete and/or weak/moderate and within greater than 10% of the invasive tumor cells or complete and circumferential membrane staining that is intense and within less than or equal to 10% of the invasive tumor cells.” In such cases, the panel recommends reflex testing using the ISH method on the same specimen or repeating tests if a new specimen is available.

Similarly, samples with equivocal results by an ISH assay (for example, single probe ISH average HER2 copy number ≥4.0 and <6.0 signals/cell; and dual probe HER2/CEP17 ratio <2.0 with an average HER2 copy number ≥4.0 signals/cell and <6.0 signals/cell) must be confirmed by reflex
testing using the IHC method on the same specimen or repeating tests if a new specimen is available.

**Treatment Approach**

The treatment of breast cancer includes the treatment of local disease with surgery, radiation therapy, or both, and systemic treatment with chemotherapy, endocrine therapy, biologic therapy, or combinations of these. The need for and selection of various local or systemic therapies are based on several prognostic and predictive factors. These factors include tumor histology, clinical and pathologic characteristics of the primary tumor, ALN status, tumor ER/PR content, tumor HER2 status, multi-gene testing, presence or absence of detectable metastatic disease, patient comorbid conditions, patient age, and menopausal status. One percent of breast cancers occur in men, and men with breast cancer should be treated similarly to postmenopausal women, except that the use of aromatase inhibitors is ineffective without concomitant suppression of testicular steroidogenesis. Patient preference is a major component of the decision-making process, especially in situations in which survival rates are equivalent among the available treatment options.
Ductal Carcinoma in Situ (Tis, N0, M0)
The recommended workup and staging of DCIS includes history and physical examination; bilateral diagnostic mammography; pathology review; determination of tumor estrogen receptor (ER) status; and MRI as indicated.

For pathology reporting, the NCCN panel endorses the College of American Pathologists Protocol for both invasive and noninvasive carcinomas of the breast.3

The NCCN panel recommends testing for ER status in order to determine the benefit of adjuvant endocrine therapy or risk reduction. Although the tumor HER2 status is of prognostic significance in invasive cancer, its importance in DCIS has not been elucidated. To date, studies have either found unclear or weak evidence of HER2 status as a prognostic indicator in DCIS.4-7 The NCCN Panel has concluded that knowing the HER2 status of DCIS does not alter the management strategy and is not required DCIS.

Genetic counseling is recommended if the patient is considered to be at high risk for hereditary breast cancer as defined by the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

The role of MRI in management of DCIS remains unclear. MRI has been prospectively shown to have a sensitivity of up to 98% for high-grade DCIS.8 In a prospective, observational study of 193 women with pure DCIS who underwent both mammography and MRI imaging preoperatively; 93 (56%) women were diagnosed by mammography and 153 (92%) were diagnosed by MRI (P < .0001). Of the 89 women with high-grade DCIS, 43 (48%) who were not diagnosed by mammography were diagnosed by MRI alone.8 However, other studies suggest that MRI can overestimate the extent of disease.9 Therefore, surgical decisions should not be solely based on MRI results especially when mastectomy is being contemplated. If MRI findings suggest more extensive disease than is seen on mammography such that a markedly larger resection is required for complete excision, the findings should be verified histologically through MRI-guided biopsy of the more extensive enhancement.

Studies have also been performed to determine whether the use of MRI reduces re-excision rates and decreases local recurrence in women with DCIS. No reduction in re-excision rates was seen in women undergoing lumpectomy following MRI compared with those who did not undergo preoperative MRI.10,11

The NCCN Panel recommends only performing breast MRI for DCIS in select circumstances where additional information is warranted during the initial workup, noting that the use of MRI has not been shown to increase likelihood of negative margins or decrease conversion to mastectomy for DCIS.

Primary Treatment for DCIS
The goal of primary therapy for DCIS is to prevent progression to invasive breast carcinoma. Management strategies for DCIS treatment include surgery (mastectomy or lumpectomy), radiation therapy, and adjuvant endocrine therapy to reduce risk of recurrence.

Surgery: Excision of DCIS using a breast-conserving approach (lumpectomy) with or without whole breast radiation therapy (WBRT) or alternatively, mastectomy, are the primary treatment options for individuals with DCIS.

The choice of local treatment does not impact overall disease-related survival; therefore, the individual patient’s acceptance of the potential for an increased risk of local recurrence must be considered. Post-excision mammography is valuable in confirming that an adequate excision of
DCIS has been performed particularly for DCIS patients who initially present with microcalcifications.12

Mastectomy: Patients with DCIS and evidence of widespread disease (ie, disease involving two or more quadrants) on diagnostic mammography or other imaging, physical examination, or biopsy may require mastectomy. Mastectomy permanently alters the lymphatic drainage pattern to the axilla, so that future performance of a sentinel lymph node biopsy (SLNB) is not technically feasible.13,14 Therefore, for DCIS patients who intend on treatment with mastectomy, or alternatively, for local excision in an anatomic location that could compromise the lymphatic drainage pattern to the axilla (eg, tail of the breast), a SLNB procedure should strongly be considered at the time of definitive surgery to avoid necessitating a full axillary lymph node dissection for evaluation of the axilla.13-16

Complete axillary lymph node dissection (ALND) is not recommended unless there is pathologically documented invasive cancer or axillary lymph node metastatic disease in patients (by either biopsy or SNLB). However, a small proportion of women (about 25%) with seemingly pure DCIS on initial biopsy will have invasive breast cancer at the time of the definitive surgical procedure17 and thus will ultimately require ALN staging.

Lumpectomy plus Whole Breast Radiation Therapy (WBRT): Breast conserving therapy (BCT) includes lumpectomy to remove the tumor with negative surgical margins followed by WBRT to eradicate any residual microscopic disease. Several prospective randomized trials of pure DCIS have shown that the addition of WBRT after lumpectomy decreases the rate of in-breast disease recurrence,18-25 or distant metastasis-free survival.26 In the long term follow-up of the RTOG 9804 trial, at 7 years, the local recurrence rate was 0.9% (95% CI, 0.0%–2.2%) in the radiation therapy arm versus 6.7% (95% CI, 3.2%–9.6%) in the observation arm (HR, 0.11; 95% CI, 0.03–0.47; P < .001). In the subset of patients with good-risk disease features, the local recurrence rate was low with observation but was decreased significantly with the addition of radiation therapy.26 A meta-analysis of four large multicenter randomized trials confirms the results of the individual trials, demonstrating that the addition of WBRT after lumpectomy for DCIS provides a statistically and clinically significant reduction in ipsilateral breast events (HR [hazard ratio], 0.49; 95% CI; 0.41–0.58, P < .00001).27 However, these trials did not show that the addition of RT has an overall survival benefit. The long-term follow-up of the NSABP B-17 showed that at 15 years, radiation therapy resulted in a 52% reduction of ipsilateral invasive recurrence compared with excision alone (HR, 0.48; 95% CI, 0.33–0.69, P < .001).24 However, overall survival (OS) and cumulative all-cause mortality rates through 15 years were similar between the two groups (HR for death, 1.08; 95% CI, 0.79–1.48).24 Similar findings were reported by a large observational study of the SEER database that included 108,196 patients with DCIS.28 In a subgroup analysis at 10 years, of 60,000 women treated with breast-conserving therapy, with or without radiation therapy, radiation therapy was associated with a 50% reduction in the risk of ipsilateral recurrence (adjusted HR, 0.47 [95% CI, 0.42–0.53]; P < .001), however, breast cancer-specific mortality was found to be similar (HR, 0.86 [95% CI, 0.67–1.10]; P = .22).28

More recently, in a population-based study, the use of WBRT in patients with higher-risk DCIS (eg higher nuclear grade, younger age, and larger tumor size) was demonstrated to be associated with a modest, but statistically significant improvement in survival.29

RT Boost: The use of RT boost has been demonstrated to provide a small but statistically significant reduction in IBTR risk (4% at 20 years) in all age groups for invasive breast cancers.30-33
Recently, a pooled analysis of patient-level data from 10 academic institutions evaluated outcomes of pure DCIS patients, all treated with lumpectomy and WBRT (n = 4131) who either received RT boost with a median dose of 14 Gy (n = 2661) or received no boost (n = 1470). The median follow-up of patients was 9 years. A decrease in IBTR was seen in patients who received boost compared with those who did not at 5 years (97.1% vs 96.3%), 10 years (94.1% vs 92.5%), and 15 years (91.6% vs 88.0%) (P = .0389 for all). The use of RT boost was associated with significantly decreased IBTR across the entire cohort of patients (hazard ratio [HR], 0.73; 95% CI, 0.57-0.94; P = .01).34 In a multivariate analysis that took into account factors associated with lower IBTR, including grade, ER positive status, use of adjuvant tamoxifen, margin status, and age, the benefit of RT boost still remained statistically significant (hazard ratio, 0.69; 95% confidence interval [CI], 0.53 - 0.91; P < .010).34 Even in patients considered very low risk based on negative margins status (defined as ink on tumor as per National Surgical Adjuvant Breast and Bowel Project definition, or margins <2 mm as per SSO/ASTRO/ASCO definition), the RT boost remained statistically significant for decreasing the rate of local relapse. Similar to invasive cancers, though RT boost was beneficial in all age groups studied, the magnitude of the absolute benefit of the boost was greatest in younger patients. Two ongoing randomized, phase 3 trials are studying whether an RT boost reduces recurrence in patients with DCIS (ClinicalTrials.gov Identifiers: NCT00470236 and NCT00907868).

While considering RT boost for DCIS, the NCCN panel recommends an individualized approach based on patient preference and other factors such as longevity.

**Lumpectomy alone without WBRT:** Several trials have examined omission of RT after lumpectomy in carefully selected, low-risk patients. There are retrospective series suggesting that selected patients have a low risk of in-breast recurrence when treated with excision alone (without WBRT).35-38 For example, in one retrospective review, 10-year disease-free survival (DFS) rates of 186 patients with DCIS treated with lumpectomy alone was 94% for patients with low-risk DCIS and 83% for patients with both intermediate- and high-risk DCIS.35

In another retrospective study of 215 patients with DCIS treated with lumpectomy without radiation therapy, endocrine therapy, or chemotherapy, the recurrence rate over 8 years was 0%, 21.5%, and 32.1% in patients with low-, intermediate- or high-risk DCIS, respectively.36

A multi-Institutional, non-randomized, prospective study of selected patients with low-risk DCIS treated without radiation has also provided some support for the use of excision without radiation in the treatment of DCIS.39 Patients were enrolled onto one of two low-risk cohorts: a) low- or intermediate-grade DCIS, tumor size 2.5 cm or smaller (n = 561); or b) high-grade DCIS, tumor size 1 cm or smaller (n = 104). Protocol specifications included excision of the DCIS tumor with a minimum negative margin width of at least 3 mm. Only 30% of the patients received tamoxifen. Of note, margins were substantially wider than the 3 mm protocol requirement in many patients (ie- the low/intermediate-risk patient group margins were ≥ 5 mm in 62% of patients and >10 mm or no tumor on re-excision in 48 % of patients).39 Although the rate of IBTR were acceptably low for the low-/intermediate grade group at the 5 years, at a median follow-up time of 12.3 years, the rates of developing an IBTR were 14.4% for low/intermediate-grade and 24.6% for high grade DCIS (P = .003). This suggests that IBTR events may be delayed but not prevented in the seemingly low-risk population. Therefore, the NCCN panel concluded that for DCIS patients treated with lumpectomy alone (without radiation), irrespective of margin width, the risk of IBTR is substantially higher than treatment with excision followed by whole breast radiation therapy (even for predefined low-risk subsets of DCIS patients).
Margin status after breast conserving therapy: Prospective randomized trials have not been carried out to analyze whether wider margins can replace the need for radiation therapy for DCIS. Results from a retrospective study of 445 patients with pure DCIS treated by excision alone indicated that margin width was the most important independent predictor of local recurrence, although the trend for decreasing local recurrence risk with increasing margin width was most apparent with margins less than 1 mm and greater than or equal to 10 mm.\textsuperscript{40} In a meta-analysis of 4660 patients with DCIS treated with breast-conserving surgery and radiation, a surgical margin of less than 2 mm was associated with increased rates of IBTR compared with margins of 2 mm, although no significant differences were observed when margins of greater than 2 mm to 5 mm or greater than 5 mm were compared with 2-mm margins.\textsuperscript{41}

A fairly recent study retrospectively reviewed a database of 2996 patients with DCIS who underwent breast-conserving surgery to investigate the association between margin width and recurrence, controlling all other characteristics.\textsuperscript{42} Wider margins were significantly associated with a lower rate of recurrence only in women who did not receive radiation therapy ($P < .0001$), but not in those treated with radiation ($P = .95$).\textsuperscript{42}

According to the 2016 guidelines by SSO/ASTRO/ASCO, the use of at least 2 mm margin in DCIS treated with WBRT is associated with low rates of ipsilateral breast tumor recurrence (IBTR).\textsuperscript{43} Additional factors to consider in assessing adequacy of excision for DCIS include presence of residual calcifications, which margin is close (anterior against skin or posterior against muscle versus medial, superior, inferior or lateral), and life expectancy of the patient. Notably, in situations where DCIS is admixed with invasive carcinoma, SSO/ASTRO/ASCO guidelines support “no tumor on ink” as an adequate margin applying to both the invasive and noninvasive components in this mixed tumor scenario.

**NCCN Recommendations for Primary Treatment of DCIS**

Trials are ongoing to determine if there might be a selected favorable biology DCIS sub-group where surgical excision is not required. Until such time that definitive evidence regarding the safety of this non-surgical approach is demonstrated, the NCCN panel continues to recommend surgical excision for DCIS. According to the NCCN Panel, primary treatment options for women with DCIS along with their respective categories of consensus are: lumpectomy plus whole breast radiation therapy with or without boost (category 1); total mastectomy, with or without SLNB with optional reconstruction (category 2A); or lumpectomy alone (category 2B). The option of lumpectomy alone should be considered only in cases where the patient and the physician view the individual as having a low risk of disease recurrence.

Contraindications to breast-conserving therapy with radiation therapy are listed in the algorithm (see *Special Considerations to Breast-Conserving Therapy Requiring Radiation Therapy* in the NCCN Guidelines for Breast Cancer). Women treated with mastectomy are appropriate candidates for breast reconstruction (see *Principles of Breast Reconstruction Following Surgery* in the NCCN Guidelines for Breast Cancer).

According to the NCCN Panel, complete resection should be documented by analysis of margins and specimen radiography. Post-excision mammography should also be performed whenever uncertainty about adequacy of excision remains. Clips are used to demarcate the biopsy area because DCIS may be clinically occult and further surgery may be required pending the margin status review by pathology.

The NCCN Panel accepts the definitions of negative margins after BCS from the 2016 SSO/ASTRO/ASCO Guidelines for DCIS.\textsuperscript{43} For pure DCIS treated by BCS and whole breast radiation therapy treatment (WBRT), margins of at least 2 mm are associated with a reduced risk of ipsilateral breast tumor recurrence (IBTR) relative to narrower negative margin widths in patients receiving WBRT. The routine practice of obtaining
negative margin widths wider than 2 mm is not supported by the evidence. An analysis of specimen margins and specimen radiographs should be performed to ensure that all mammographically detectable DCIS has been excised. In addition, a post-excision mammogram should be considered where appropriate (e.g., the mass and/or microcalcifications are not clearly within the specimen).

**Management of DCIS after Primary Treatment**

DCIS falls between atypical ductal hyperplasia and invasive ductal carcinoma within the spectrum of breast proliferative abnormalities. The Breast Cancer Prevention Trial performed by National Surgical Adjuvant Breast and Bowel Project (NSABP) showed a 75% reduction in the occurrence of invasive breast cancer in patients with atypical ductal hyperplasia treated with tamoxifen.\(^{44,45}\) These data also showed that tamoxifen led to a substantial reduction in the risk of developing benign breast disease.\(^{46}\) The Early Breast Cancer Trialists’ Collaborative Group (EBCTCG) overview analysis showed that, with 5 years of tamoxifen therapy, women with ER-positive or receptor-unknown invasive tumors had a 39% reduction in the annual odds of recurrence of invasive breast cancer.\(^{47}\)

Similarly, the NSABP B-24 trial found a benefit from tamoxifen for women with DCIS after treatment with breast conservation surgery and radiation therapy. In that study, women with DCIS who were treated with breast-conserving therapy were randomized to receive placebo or tamoxifen. At a median follow-up of 13.6 years, patients who received tamoxifen had a 3.4% absolute reduction in ipsilateral in-breast tumor recurrence risk (HR, 0.30; 95% CI, 0.21–0.42; \(P < .001\)) and a 3.2% absolute reduction in contralateral breast cancers (HR, 0.68; 95% CI, 0.48–0.95; \(P = .023\)).\(^{24}\) The women receiving tamoxifen had a 10-year cumulative rate of 4.6% for invasive and 5.6% for noninvasive breast cancers in the ipsilateral breast compared with 7.3% for invasive and 7.2% for noninvasive breast cancers in placebo-treated women. The cumulative 10-year frequency of invasive and noninvasive breast cancer in the contralateral breast was 6.9% and 4.7% in the placebo and tamoxifen groups, respectively. No differences in OS were noted. A retrospective analysis of ER expression in NSABP B-24 suggests that increased levels of ER expression predict for tamoxifen benefit in terms of risk reduction for ipsilateral and contralateral breast cancer development following breast-conserving therapy.\(^{48}\)

A phase III trial for women with excised DCIS randomized subjects in a 2 x 2 fashion to tamoxifen or not and whole breast radiation therapy or not.\(^{23}\) With 12.7 years of median follow-up, the use of tamoxifen decreased all new breast events (HR, 0.71; 95% CI, 0.58–0.88; \(P = .002\)). The use of tamoxifen decreased ipsilateral and contralateral breast events in the subjects not given whole breast radiotherapy (ipsilateral HR, 0.77; 95% CI, 0.59–0.98; contralateral HR, 0.27; 95% CI, 0.12–0.59), but not in those receiving whole breast radiotherapy (ipsilateral HR, 0.93; 95% CI, 0.50–1.75; \(P = .80\); contralateral HR, 0.99; 95% CI, 0.39–2.49; \(P = 1.0\)).

In women with ER-positive and/or PR-positive DCIS treated by wide local excision with or without breast radiotherapy, a large, randomized, double-blind, placebo-controlled trial (IBIS-II) compared anastrozole (\(n = 1471\)) with tamoxifen (\(n = 1509\)). The results demonstrated non-inferiority of anastrozole to tamoxifen.\(^{49}\) After a median follow-up of 7.2 years, 67 recurrences were reported with anastrozole versus 77 for tamoxifen; HR 0.89 [95% CI, 0.64–1.23]. A total 33 deaths were recorded for anastrozole and 36 for tamoxifen; HR 0.9393 [95% CI, 0.58–1.50, \(P = .78\)].\(^{49}\) Although the number of women reporting any adverse event was similar between anastrozole (1323 women, 91%) and tamoxifen (1379 women, 93%); the side-effect profiles of the two drugs were different. There were more fractures, musculoskeletal events, hypercholesterolemia, and strokes reported with anastrozole and more muscle spasms, gynecological
cancers and symptoms, vasomotor symptoms, and deep vein thromboses reported with tamoxifen.

The NSABP B-35 study randomly assigned 3,104 postmenopausal patients to tamoxifen or anastrozole for 5 years. All patients received breast radiotherapy. Prior to being randomly assigned, patients were stratified by age—younger or older than age 60. The primary endpoint was breast cancer–free interval. Anastrozole treatment resulted in an overall statistically significant decrease in breast cancer-free interval events compared with tamoxifen (HR, 0.73 [95% CI, 0.56–0.96], P = .0234). The significant difference in breast cancer-free interval between the two treatments was apparent in the study only after 5 years of follow-up. The estimated percentage of patients with a 10-year breast cancer-free interval was 89.1% in the tamoxifen group and 93.1% in the anastrozole group.

In addition, anastrozole resulted in further improvement in breast cancer-free interval, in younger postmenopausal patients (less than 60 years old). With respect to adverse effects, the overall incidence of thrombosis or embolism was higher in the tamoxifen group while the anastrozole group had slightly more cases of arthralgia and myalgia.

The results of the IBIS-II and the NSAP-B-35 studies indicate that anastrozole provides at least a comparable benefit as adjuvant treatment for postmenopausal women with hormone-receptor-positive DCIS, with a different toxicity profile.

NCCN Recommendations for Management of DCIS after Primary Treatment

According to the NCCN Panel, endocrine therapy, with tamoxifen (for premenopausal and postmenopausal women) or an aromatase inhibitor (for postmenopausal women especially those under 60 years of age or in those with concerns of embolism), may be considered as a strategy to reduce the risk of ipsilateral breast cancer recurrence in women with ER-positive DCIS treated with breast-conserving therapy (category 1 for those undergoing breast-conserving surgery followed by radiation therapy; category 2A for those undergoing excision alone). The benefit of endocrine therapy for ER-negative DCIS is not known.

Surveillance after treatment for DCIS helps early recognition of disease recurrences (either DCIS or invasive disease) and evaluation and management of therapy-related complications. The majority of recurrences of DCIS are in-breast recurrences after breast-conserving therapy, and recurrences mostly occur in close proximity to the location of the prior disease. Overall, approximately one-half of the local recurrences after initial treatment for a pure DCIS are invasive in nature, whereas the remainder recur as pure DCIS. According to the NCCN Panel, follow-up of women with DCIS includes interval history and physical examination every 6 to 12 months for 5 years and then annually, as well as yearly diagnostic mammography. In patients treated with breast-conserving therapy, the first follow-up mammogram should be performed 6 to 12 months after the completion of breast-conserving radiation therapy (category 2B). Patients receiving risk reduction agents should be monitored as described in the NCCN Guidelines for Breast Cancer Risk Reduction.
Invasive Breast Cancer (T0–3,N1,M0 and T1–3,N0–1,M0)

Workup

The recommended workup of localized invasive breast cancer includes: history and physical exam; bilateral diagnostic mammography; breast ultrasonography, if necessary; determination of tumor HR status (ER and PR determinations); determination of HER2-receptor status; and pathology review. Complete blood count (CBC) and liver function tests (LFTs) have no added benefit in the detection of underlying metastatic disease in asymptomatic early-stage breast cancer patients.\(^51\) In addition, monitoring of disease relapse with any tumor markers is not recommended.

Use of MRI is optional and is not universally recommended by experts in the field. Breast MRI advocates note its high sensitivity for evaluation of extent of disease, particularly for invasive cancer and in dense breasts where mammographically occult disease is more likely to elude preoperative detection. MRI detractors note that MRI has a high percentage of false-positive findings resulting in further diagnostic workup in many circumstances including MRI-guided biopsy.\(^52-54\) MRI findings tend to overestimate extent of disease\(^55\) resulting in increased frequency of mastectomies.\(^56-59\)

MRI findings alone are insufficient to determine whether breast conservation therapy is optimal as additional tissue sampling is needed to verify true malignant disease warranting excision. MRI use may increase mastectomy rates by identifying mammographically occult disease satellites that would have been adequately treated with post-lumpectomy radiation had the disease remained undiscovered without MRI.\(^59\)

Two prospective randomized studies have examined the utility of pre-operative MRI in determining disease extent, and neither demonstrated improvement in rates of post-lumpectomy re-excision.\(^60,61\)

Retrospective review of utility MRI showed conflicting outcome results, one with benefit\(^62\) and another without.\(^63\) One systematic review\(^64\) documented that breast MRI staging altered surgical treatment in 7.8% to 33.3% of women,\(^54\) however no differences in local recurrence or survival have yet been demonstrated. In addition, there is no evidence that use of breast MRI increases rates of margin-negative resection.\(^64,65\)

If breast MRI imaging is performed, a dedicated breast coil, an imaging team experienced with breast MRI guided biopsy, and multidisciplinary treatment team are the standard of care. Clinically positive axillary nodes and occult primary breast cancer or Paget’s disease of the nipple with breast primary not identified on mammography, ultrasound, or physical examination are specific indications for breast MRI imaging. MRI may also be useful for the evaluation of breast cancer response to preoperative systemic therapy and to assess the potential for breast-conserving therapy.

Pathology Assessment: Full knowledge of extent of disease and biologic features is central to the treatment of breast cancer. Several factors contribute to the determination of the disease staging, recurrence risk assessment, and predictive response (ie, ER, PR, HER2). The excised tissue detailing the written pathology report details these key factors. The accuracy of pathology reporting requires communication between the clinician and the pathologist relating pertinent patient history, prior breast biopsies, prior chest irradiation, pregnancy status, biopsy characteristics (ie, palpable, mammographically detected microcalcifications), clinical state of lymph nodes, presence of inflammatory change or other skin abnormality, and any prior treatment administered (ie, chemotherapy, radiation therapy). The specimens should be oriented for the pathologist, and specific requests for determination of biomarkers should be stated (eg, ER, PR, and HER2 status). Data from both national and local surveys show that as many as 50% of pathology reports for breast cancer are...
missing some elements critical to patient management. Significant omissions include failure to orient and report surgical margins and failure to report tumor grade consistently. CAP has developed pathology reporting protocols to promote complete and standardized reporting of malignant specimens (www.cap.org). The NCCN Breast Cancer Panel endorses the use of the CAP protocols for reporting the pathologic analysis of all breast cancer specimens.

Genetic counseling: For patients considered to be at high risk for hereditary breast cancer as defined by the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian, genetic counseling is recommended.

Distress Assessment: Levels of distress may vary in patients and should be addressed individually. Psychological distress can be impacted by body image and other factors. Younger women have higher rates of psychosocial distress than women diagnosed at older ages. The NCCN Breast Cancer Panel recommends assessing for distress in patients newly diagnosed with breast cancer.

Fertility Counseling: Numerous epidemiologic studies have demonstrated that child-bearing after treatment for invasive breast cancer does not increase rates of recurrence or death from breast cancer. The offspring of pregnancies after treatment for breast cancer do not have an increased rate of birth defects or other serious childhood illness. However, treatment for breast cancer, especially with cytotoxic agents, may impair fertility.

Many women, especially those younger than age 35, regain menstrual function within 2 years of completing chemotherapy. Resumption of menses does not necessarily correlate with fertility, and fertility may be preserved without menses. All premenopausal patients should be informed about the potential impact of chemotherapy on fertility and asked about their desire for potential future pregnancies.

A decision for fertility preservation should include multiple factors such as patient preference, tumor stage and biology, age of the patient, risk of premature ovarian failure based on anticipated type and duration of chemotherapy and/or endocrine therapy, as well as the timing and duration allowed for fertility preservation.

Several studies report lower rates of fertility discussion among female patients with cancer despite the updated ASCO guidelines stating that patients should not be excluded from consideration for discussion of fertility preservation for any reason, including parity, prognosis, age, and socioeconomic status. The NCCN Panel recommends that all women of childbearing potential should have a discussion with their treating physicians. Patients who desire to bear children after systemic therapy should be referred to a fertility specialist prior to initiating systemic (chemotherapy or endocrine) therapy.

Randomized trials have demonstrated that GnRH agonists (such as goserelin) administered prior to initiating chemotherapy and then administered concurrently with adjuvant chemotherapy protect against ovarian failure and reduce the risk of early menopause. In one trial goserelin improved the probability of pregnancy from 11% to 21% in patients with HR-negative early-stage breast cancer. Smaller historical experiences in patients with HR-positive disease have conflicting results with respect to the protective effects of GnRH agonists in fertility preservation.

Patients should be informed of all the various modalities available to minimize gonadal damage and preserve ovarian function and future fertility. The fertility specialist should discuss specifics of fertility preservation options inclusive of types of hormonal interventions and risks involved with ovarian stimulation, embryo or oocyte cryopreservation, and other investigational options, as well as the probability of successful gestation and childbirth.
Combining the various modalities for a specific patient may increase the odds of preservation of future fertility. It is important for fetal safety that women actively avoid becoming pregnant during breast cancer treatment. Also see NCCN Guidelines for Adolescent and Young Adult Oncology.

**Additional Workup**
The panel has re-iterated that routine systemic imaging is not indicated for patients with early breast cancer in the absence of signs/symptoms of metastatic disease. These recommendations are based on studies showing no additional value of these tests in patients with early-stage disease. In one study, metastases were identified by bone scan in 5.1%, 5.6%, and 14% of patients with stage I, II, and III disease, respectively, and no evidence of metastasis was detected by liver ultrasonography or chest radiography in patients with stage I or II disease. For patients with stage III breast cancer, the prevalence of a positive liver ultrasound and positive chest x-ray was 6% and 7%, respectively.

For patients presenting with disease confined to the breast (stage I to II) the NCCN Panel does not recommend routine systemic imaging in the absence of signs or symptoms suspicious for metastatic disease. According to the panel, additional tests may be considered in patients who present with locally advanced (T3 N1-3 M0) disease and in those with signs or symptoms suspicious for metastatic disease.

CBCs and LFTs may be considered if the patient is a candidate for preoperative systemic therapy, or if otherwise clinically indicated. Additional tests may be considered only based on the signs and symptoms.

A chest diagnostic CT is indicated only if pulmonary symptoms (ie, cough or hemoptysis) are present. Likewise, abdominal imaging using diagnostic CT or MRI is indicated if the patient has elevated alkaline phosphatase, abnormal results on LFTs, abdominal symptoms, or abnormal physical examination of the abdomen or pelvis.

A bone scan is indicated in patients presenting with localized bone pain or elevated alkaline phosphatase. The use of PET or PET/CT scanning is not indicated in the staging of clinical stage I, II, or operable III (T3 N1) breast cancer. The recommendation against the use of PET scanning is supported by the high false-negative rate in the detection of lesions that are small (<1 cm) and/or low grade, the low sensitivity for detection of axillary nodal metastases, the low prior probability of these patients having detectable metastatic disease, and the high rate of false-positive scans.

FDG PET/CT is most helpful in situations where standard staging studies are equivocal or suspicious, especially in the setting of locally advanced or metastatic disease.

**Locoregional Treatment**

**Surgery**
In general, patients with early-stage breast cancer undergo primary surgery (lumpectomy or mastectomy) with or without radiation therapy. Following local treatment, adjuvant systemic therapy may be offered based on primary tumor characteristics, such as tumor size, grade, lymph node involvement, ER/PR status, and expression of HER2-receptor.

Several randomized trials document that mastectomy is equivalent to breast-conserving therapy (lumpectomy with whole breast irradiation) with respect to overall survival as primary breast local treatment for the majority of women with stage I and stage II breast cancers (category 1).

After surgical resection, a careful histologic assessment of resection margins is essential. The NCCN Panel notes that benefit of lumpectomy is predicated on achieving pathologically negative margins after resection.
The NCCN Panel accepts the most recent definition outlined in the guidelines established by the Society of Surgical Oncology (SSO)/American Society for Radiation Oncology (ASTRO) of no ink on a tumor as the standard for negative surgical margins for invasive cancer (with or without a component of DCIS).104

If margins remain positive after further surgical re-excision(s), then mastectomy may be required for optimal local disease control.

In order to adequately assess margins following surgery, the panel recommends that the surgical specimens be directionally oriented and that the pathologist provide descriptions of the gross and microscopic margin status and the distance, orientation, and type of tumor (invasive cancer or pure DCIS) in relation to the closest margin. Marking the tumor bed with clips facilitates accurate planning of the radiation boost field, where appropriate. It may be reasonable to treat selected patients with invasive cancer (without extensive intraductal component) despite a microscopically focally positive margin with breast conservation therapy.

Breast Conserving Therapy (Lumpectomy)

Lumpectomy allows patients to preserve their breast without sacrificing oncologic outcome. Lumpectomy is contraindicated for patients who are pregnant and would require radiation during pregnancy; have diffuse suspicious or malignant-appearing microcalcifications on mammography; have widespread disease that cannot be incorporated by local excision through a single incision with a satisfactory cosmetic result; or have diffusely positive pathologic margins. Relative contraindications to lumpectomy include previous radiation therapy to the breast or chest wall; active connective tissue disease involving the skin (especially scleroderma and lupus), tumors greater than 5 cm (category 2B), and positive pathologic margins.

Several studies of women with early-stage breast cancer treated with lumpectomy have identified young age as a significant predictor of an increased likelihood of ipsilateral breast tumor recurrences after lumpectomy.105-107 Risk factors, such as a family history of breast cancer or a genetic predisposition for breast cancer (i.e., BRCA1/2 or other cancer predisposing mutation), are more likely to exist in the population of young women with breast cancer, thereby confounding the independent contributions of age and treatment to clinical outcome.108 Studies have shown that survival outcomes for young women with breast cancer receiving either lumpectomy or mastectomy are similar.101,102,109-111 Some recent studies show improved survival112-114 and fewer post-surgical complications115 with lumpectomy.

Mastectomy

Mastectomy is indicated for patients who are not candidates for lumpectomy and those who choose to undergo this procedure over lumpectomy.

Only limited data are available on the survival impact of risk reducing contralateral mastectomy in women with a unilateral breast cancer.116 Analysis of women included in the SEER database treated with mastectomy for a unilateral breast cancer from 1998 to 2003 showed that contralateral mastectomy performed at the time of treatment of a unilateral cancer was associated with a reduction in breast cancer-specific mortality only in the population of young women (18–49 years of age) with stage I/II, ER-negative breast cancer (HR, 0.68; 95% CI, 0.53–0.88; \( P = .004 \)).117 The 5-year breast cancer survival for this group was slightly improved with contralateral mastectomy versus without (88.5% vs. 83.7%, difference = 4.8%).117 These differences observed in retrospective analysis could be due to selection bias among patients who chose risk reducing contralateral mastectomy.118 A statistical simulation of survival outcomes after risk reducing contralateral mastectomy among women with stage I or II breast
cancer with no BRCA mutation found that the absolute 20-year survival benefit from risk reducing contralateral mastectomy was less than 1% among all age, ER status, and cancer stage groups.\textsuperscript{119} Data from a recent meta-analysis found no absolute reduction in risk of distant metastases with RRM.\textsuperscript{120} Furthermore, among patients with unilateral breast cancer who have an increased familial/genetic risk, although a decrease in metastatic contralateral breast cancer incidence was observed in those who received risk reducing contralateral mastectomy, no improvement was seen in OS of these patients.\textsuperscript{120}

The panel recommends that women with breast cancer who are less than or equal to 35 years or premenopausal and carriers of a known BRCA1/2 mutation consider additional risk reduction strategies following appropriate risk assessment and counseling (see NCCN Guidelines for Breast Risk Reduction and NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian). This process should involve multidisciplinary consultations prior to surgery, and should include a discussion of the risks associated with development of a contralateral breast cancer as compared with the risks associated with recurrent disease from the primary cancer. Except as specifically outlined in these guidelines, risk reduction mastectomy of a breast contralateral to a known unilateral breast cancer treated with mastectomy is discouraged by the panel. The use of a prophylactic mastectomy contralateral to a breast treated with lumpectomy is very strongly discouraged in all patients.

The NCCN panel recommends referring to the NCCN Guidelines for Older Adult Oncology for special considerations for this population.

**Surgical Axillary Staging**

Axillary lymph node dissection is the standard of care for patients with clinically positive nodes. However, ALND is associated with lymphedema and other significant morbidities,\textsuperscript{121-123} and therefore sentinel lymph node biopsy (SLNB) has replaced axillary evaluation for clinically node negative patients.

Based on several randomized trials, it is now accepted that patients with a negative sentinel node do not need an ALND.\textsuperscript{124-127}

The ACOSOG Z0011 trial randomized women greater than or equal to 18 years of age with T1/T2 tumors, fewer than 3 positive sentinel lymph nodes (SLNs), undergoing lumpectomy and whole breast radiation therapy (WBRT) to SLNB alone (n = 436) or to ALND (n = 420). In this study, there was no difference in local recurrence, disease-free survival (DFS), or overall survival (OS) between women with positive SLN undergoing a completion ALND versus no ALND. Only ER-negative status, age less than 50, and lack of adjuvant systemic therapy were associated with decreased OS.\textsuperscript{128} At a median follow-up of 6.3 years, locoregional recurrences were noted in 4.1% of patients in the ALND group and 2.8% of patients in the SLNB patients (P = .11). Median OS was approximately 92% in each group.\textsuperscript{129} Long term follow-up (median 9.25 years) results of the ACOSOG Z0011 study showed no statistically significant difference in local recurrence-free survival (RFS) between arms of the trial (P = .13).\textsuperscript{130} The cumulative incidence of ipsilateral axillary recurrences at 10 years was 0.5% (2 patients) in those who underwent ALND and 1.5% (5 patients) in those who underwent SLNB-alone (P = .28).\textsuperscript{130} The 10-year cumulative incidence of local regional recurrences was 6.2% with ALND and 5.3% with SLNB alone (P = .36).\textsuperscript{130} The results of the ACOSOG Z0011 trial show that that ALND is not needed in women with early-stage breast cancer who have only one or two sentinel lymph node metastases who will receive whole-breast RT as part of breast-conserving therapy.

Another randomized trial (IBCSG 23-01) was specifically designed to compare outcomes in patients with sentinel micrometastases (≤2 mm) treated with ALND versus no ALND.\textsuperscript{131} While the ACOSOG Z0011 trial was limited to those undergoing BCT, this trial included patients
undergoing mastectomy (9%).\textsuperscript{131} Between the group treated with ALND versus the group that was not treated with ALND, there were no differences in 5 year DFS (84.4%; 95% CI 80.7%–88.1% versus 87.8%; 95% CI 84.4%–91.2%), cumulative incidence of breast cancer events - including local, regional, contralateral breast, and distant recurrence (10.8%; 95% CI 7.6–14.0 versus 10.6%; 95% CI 7.5–13.8) or OS (97.6%; 95% CI 96.0%–99.2% versus 97.5%; 95% CI 95.8%–99.1%).\textsuperscript{131} Regional recurrence was less than 1% for those who underwent ALND and 1% for those who did not undergo ALND.\textsuperscript{131} The results of this trial show that in patients with only micrometastases in the sentinel nodes, ALND is not needed.

The results of a trial by the European EORTC group (AMAROS) assessed whether axillary RT provides regional control with fewer side-effects compared with ALND.\textsuperscript{132} This trial included patients (n = 4823) with T1 or T2 breast cancer and positive SLN (micrometastatic or macrometastatic) and included a small fraction of patients (n = 248) treated with mastectomy.\textsuperscript{132} The results reported no difference in five-year OS or DFS for patients randomized to ALND versus axillary radiation.\textsuperscript{132} The 5-year DFS was 86.9% (95% CI 84.1–89.3) in the ALND group and 82.7% (79.3–85.5) in the axillary radiotherapy group. The 5-year OS was 93.3% (95% CI 91.0–95.0) in the ALND group and 92.5% (90.0–94.4) in the axillary radiotherapy group.\textsuperscript{132} At the end of 5 years, lymphedema was less frequent in the group treated with axillary RT versus ALND (11% vs. 23%).\textsuperscript{132} The results of this trial show that axillary radiation is an acceptable alternative to ALND for axillary control in patients found to have positive sentinel nodes, with significantly less lymphedema related morbidity.

If axillary lymph nodes are clinically negative at the time of diagnosis or if FNA/core biopsy results of suspicious nodes is negative, the panel recommends SLN mapping and excision. SLNs can be assessed for the presence of metastases by both hematoxylin and eosin (H&E) staining and cytokeratin IHC. The clinical significance of a lymph node that is negative by H&E staining but positive by cytokeratin IHC is not clear. Because the historical and clinical trial data on which treatment decisions are based have relied on H&E staining, the panel does not recommend routine cytokeratin IHC to define node involvement and believes that current treatment decisions should be made solely on H&E staining. This recommendation is further supported by a randomized clinical trial (ACOSOG Z0010) for patients with H&E negative nodes where further examination by cytokeratin IHC was not associated with improved OS over a median of 6.3 years.\textsuperscript{136} In the uncommon situation in which H&E staining is equivocal, reliance on the results of cytokeratin IHC is appropriate.

**NCCN Recommendations for Surgical Axillary Staging:** In patients with clinically positive nodes, to determine whether axillary lymph node ALND is needed, the panel recommends pathologic confirmation of malignancy using ultrasound-guided fine-needle aspiration (FNA)\textsuperscript{133} or core biopsy of suspicious nodes. According to the NCCN panel, the recommendation for axillary dissection of level I and II nodes is limited to patients with biopsy proven axillary metastases. Traditional level I and level II axillary lymph nodes (ALN) requires that at least 10 lymph nodes be provided for pathologic evaluation to accurately stage the axilla.\textsuperscript{134,135} ALND should be extended to include level III nodes only if gross disease is apparent in the level II and III nodes. In the absence of gross disease in level II nodes, lymph node dissection should include tissue inferior to the axillary vein from the latissimus dorsi muscle laterally to the medial border of the pectoralis minor muscle (level I and II).

**Discussion:** In the absence of gross disease in level II and III nodes, the panel does not recommend routine cytokeratin IHC to define node involvement and believes that current treatment decisions should be made solely on H&E staining. This recommendation is further supported by a randomized clinical trial (ACOSOG Z0010) for patients with H&E negative nodes where further examination by cytokeratin IHC was not associated with improved OS over a median of 6.3 years. In the uncommon situation in which H&E staining is equivocal, reliance on the results of cytokeratin IHC is appropriate.

Based on the ACOSOG Z0011 trial results, for patients with T1 or T2 tumors, 1 to 2 positive SLNs, treated with lumpectomy but no preoperative systemic therapy and for whom receive WBRT, the NCCN panel recommends no further axillary surgery. If any of the above criteria are not
met, the panel recommends level I and II axillary dissection. In the 2017 version of the NCCN guidelines, based on the results of the IBCSG 23-01 trial, the NCCN panel recommends no ALND for patients with positive SLN when that disease is only micrometastatic. According to the American Joint Committee on Cancer (AJCC) staging, micrometastatic nodal involvement is defined as a metastatic deposit >0.2 mm but ≤ 2.0 mm.137

When sentinel nodes are not successfully identified, the panel recommends level I and II axillary dissection be performed for axillary staging.

For patients undergoing mastectomy with clinically negative axillae but with positive SLNs, the panel notes that for regional control of disease axillary radiation may replace ALND.

**Radiation Therapy**

**Principles of Radiation Therapy**

**Planning techniques, Targets, and Doses**

It is important to individualize radiation therapy planning and delivery. CT based treatment planning is encouraged to delineate target volumes and adjacent organs at risk. Greater target dose homogeneity and sparing of normal tissues can be accomplished using compensators such as wedges, forward planning using segments, and intensity-modulated radiation therapy (IMRT). Respiratory control techniques including deep inspiration breath-hold and prone positioning may be used to try to further reduce dose to adjacent normal tissues, in particular heart and lung.142 Radiation boost treatment in the setting of breast conservation can be delivered using enface electrons, photons, or brachytherapy.

**Dose and fractionation:**

Four randomized clinical trials have investigated hypofractionated whole breast radiation schedules (39–42.9 Gy in single fractions of 2.6–3.3 Gy) compared to standard 50 Gy in single fractions of 2 Gy.143-146 The 10-year follow-up data from the START trials147 are consistent with the 10-year results of the Canadian trial,146 which reported that local tumor control and breast cosmesis were similar with a regimen of 42.5 Gy in 16 fractions over 3.2 weeks compared with 50 Gy in 25 fractions over 5 weeks.146 The START trials reported radiation-related effects to normal breast tissue such as breast shrinkage, telangiectasia, and breast edema as less
common with the hypofractionated fraction regimen.\textsuperscript{147} The NCCN Panel recommends for whole breast irradiation, a dose of 46–50 Gy in 23-25 fractions or 40–42.5 Gy in 15–16 fractions. Based on convenience and the data from the START trials,\textsuperscript{147} the short course of radiation therapy (40–42.5 Gy in 15–16 fractions) is the NCCN preferred option in patients being given radiation treatment to the breast only. A boost to the tumor bed is recommended in patients with higher risk characteristics (such as age <50, high-grade disease, or patients with focally positive margins) in order to reduce local relapse.\textsuperscript{30,32,139,147-149} Typical boost doses are 10-16 Gy in 4-8 fractions.

Chest Wall Radiation (including breast reconstruction):
The target includes the ipsilateral chest wall, mastectomy scar, and drain sites when indicated. Depending on whether the patient has had breast reconstruction, several techniques using photons and/or electrons are appropriate. The NCCN panel recommends dose of 46-50 Gy in 23-25 fractions to the chest wall. A boost at the scar at the dose of 2 Gy per fraction to a total dose of approximately 60 Gy may be considered in some cases based on risk.

Regional Nodal Irradiation
The NCCN Guidelines include updated recommendations for regional lymph node irradiation in patients treated with lumpectomy and mastectomy depending on lymph node involvement (see Principles of Radiation Therapy in the NCCN Guidelines for Breast Cancer).

Two studies, MA.20 and EORTC 22922/10925 evaluated the addition of regional nodal irradiation to the internal mammary nodes and the upper axillary nodes including the supraclavicular region, in addition to whole breast irradiation or chest wall irradiation after lumpectomy or mastectomy respectively. In MA.20, regional recurrences were reduced from 2.7% with breast irradiation only to 0.7% with the addition of nodal irradiation.\textsuperscript{150} The distant recurrences were reduced from 17.3% to 13.4%.\textsuperscript{150} An improvement in disease-free survival was seen from 77% to 82% at 10 years in those who received regional nodal irradiation compared to those who did not.\textsuperscript{150} In EORTC 22922/10925, regional radiation therapy reduced the incidence of regional recurrences from 4.2% to 2.7% and decreased the rate of distant metastases from 19.6% to 15.9% at a median follow-up of 10.9 years.\textsuperscript{151}

Accelerated Partial Breast Irradiation
Several studies have been reported using accelerated partial breast irradiation (APBI) rather than whole breast irradiation following complete surgical excision of in-breast disease. The panel generally views the use of APBI as investigational, and encourages its use within the confines of a high-quality, prospective clinical trial.\textsuperscript{152} For patients who are not trial eligible, recommendations from ASTRO indicate that APBI may be suitable in selected patients with early-stage breast cancer and may be comparable to treatment with standard whole-breast RT.\textsuperscript{153} Patients who may be suitable for APBI are women 60 years of age and older who are not carriers of a known BRCA1/2 mutation and who have been treated with primary surgery for a unifocal stage I, ER-positive cancer. Tumors should be infiltrating ductal or have a favorable histology, should not be associated with an extensive intraductal component or LCIS, and should have negative margins. Thirty-four Gy in 10 fractions delivered twice per day with brachytherapy or 38.5 Gy in 10 fractions delivered twice per day with external beam photon therapy to the tumor bed is recommended. Other fractionation schemes are under investigation. Studies have suggested that the ASTRO stratification guidelines may not adequately predict ipsilateral breast tumor recurrences following APBI.\textsuperscript{154,155} Follow-up is limited and studies are ongoing.

Radiation Therapy in Patients Receiving Preoperative Systemic Therapy
The panel recommends that decisions related to administration of radiation therapy for patients receiving preoperative systemic chemotherapy should be made based on maximal stage from pre-chemotherapy tumor characteristics and/or pathological stage, irrespective of tumor response to preoperative systemic therapy.

**Adjuvant Radiation Therapy after Lumpectomy**

After lumpectomy, whole breast irradiation is strongly recommended with or without boost to tumor bed for node-positive disease (Category 1 for those with positive nodes; category 2 A for those with negative axillary nodes). This recommendation is supported by the results of a meta-analysis by the EBCTCG showing reduction in 10-year risk of recurrence in those who received whole breast irradiation versus those who did not (19% vs. 35%; RR 0.52, 95% CI 0.48-0.56). In addition, a significant reduction in 15-year risk of breast cancer death (21% vs. 25%; RR 0.82, 95% CI 0.75-0.90) was also observed.

**Regional Nodal Irradiation after lumpectomy**

The reduction in recurrence the risk of locoregional and distant recurrence and improvement in disease-free survival seen in the MA.20 and EORTC 22922/10925 trials, support the importance of regional nodal irradiation after lumpectomy. The NCCN panel strongly recommends irradiation of infracavicular and supraclavicular areas, internal mammary nodes and any part of the axillary bed that may be suspicious (category 1 for greater than or equal to 4 positive nodes). Irradiation of the regional nodal area is generally not recommended by the panel for those with negative axillary nodes.

If adjuvant chemotherapy is indicated after lumpectomy, radiation should be given after chemotherapy is completed. This recommendation is based on results of the “Upfront-Outback” trial in which patients who had undergone breast-conserving surgery and axillary dissection were randomly assigned to receive chemotherapy following radiation therapy or radiation therapy following chemotherapy. The initial results showed an increased rate of local recurrence in the group with delayed radiotherapy at a median follow-up of 58 months; however, differences in rates of distant or local recurrence were not statistically significant when the two arms were compared at 135-month follow-up.

**Radiation Therapy after Lumpectomy in Older Adults**

Whole breast irradiation as a component of breast-conserving therapy is not always necessary in selected women 70 years of age or older. In a study of women with clinical stage I, ER-positive breast cancer who were greater than or equal to 70 years of age at diagnosis, patients were randomized to receive lumpectomy with whole breast radiation or lumpectomy alone, both with tamoxifen for five years. Locoregional recurrence rates were 1% in the lumpectomy, radiation, and tamoxifen arm and 4% in the lumpectomy plus tamoxifen arm. There were no differences in OS, DFS, or need for mastectomy. These results were confirmed in an updated analysis of this study with a median follow-up of 12.6 years. At 10 years, a statistically significant reduction in IBTR was seen with radiation therapy with 90% of patients in the lumpectomy and tamoxifen arm compared with 98% in the lumpectomy plus radiation and tamoxifen arm were free from locoregional recurrence. Whether the difference in tumor control is clinically significant and the patient receives breast radiotherapy should be individualized based upon discussion between the patient and her care team.

The NCCN Guidelines allow for the use of lumpectomy (pathologically negative margin required) plus tamoxifen or an aromatase inhibitor without breast irradiation in women greater than or equal to 70 years of age with clinically negative lymph nodes and ER-positive, T1 breast cancer (category 1).
Adjuvant Radiation Therapy after Mastectomy

Node-Positive Disease: Randomized clinical trials have shown that a DFS and OS advantage is conferred by the irradiation of chest wall and regional lymph nodes in women with positive ALNs after mastectomy and ALN dissection. In these trials, the ipsilateral chest wall and the ipsilateral locoregional lymph nodes were irradiated. The results of EBCTCG meta-analyses show that radiotherapy after mastectomy and axillary node dissection reduced both recurrence and breast cancer mortality in the women with 1 to 3 positive lymph nodes even when systemic therapy was administered. Based on these studies, the current guidelines recommend postmastectomy chest wall irradiation in women positive ALNs (Category 1). Two retrospective analyses have provided evidence for benefit of radiation therapy for only selected patients (patients presenting with clinical stage III disease and patients with four or more positive nodes) receiving preoperative systemic therapy prior to mastectomy.

Regional Nodal Irradiation after mastectomy

The use of regional nodal irradiation for patients undergoing mastectomy is supported by a subgroup analysis of studies from the Danish Breast Cancer Cooperative Group. In this analysis, a substantial survival benefit was associated with postmastectomy radiation therapy for women with 1 to 3 positive ALNs. In addition, data from the EORTC 22922/10925 trial supports the role of regional RT in this population based on the inclusion of patients who had undergone mastectomy in this study. Based on the above data, the NCCN panel recommends irradiation of infraclavicular and supraclavicular areas, internal mammary nodes and any part of the axillary bed that may be suspicious (category 1 for greater than or equal to 4 positive nodes; 2A for 1-3 positive nodes).

Node-Negative Disease: Features in node-negative tumors that predict a high rate of local recurrence include primary tumors greater than 5 cm or positive pathologic margins. Chest wall irradiation is recommended for these patients. Consideration should be given to radiation to the ipsilateral supraclavicular area and to the ipsilateral internal mammary lymph nodes, especially in patients tumors greater than 5 cm, or positive surgical margins. In patients with tumors less than or equal to 5 cm and negative margins but less than or equal to 1 mm, chest wall irradiation should be considered.

In patients with negative nodes, tumor less than or equal to 5 cm, and clear margins (≥1 mm), post-mastectomy radiation therapy is usually not recommended. However, the panel has noted that it may be considered only for patients with high risk of recurrence. A retrospective analysis suggests benefit of post-mastectomy radiation therapy in reducing risk of recurrence in patients with node-negative disease with high-risk factors such as close margins, tumors greater than or equal to 2 cm, premenopausal status, and lymphovascular invasion. Another study showed increased risk of locoregional recurrence in women with node-negative triple-negative breast cancer with tumors less than or equal to 5 cm.
Breast Reconstruction
Breast reconstruction may be an option for any woman receiving surgical treatment for breast cancer. Therefore, all women undergoing breast cancer treatment should be educated about breast reconstructive options as adapted to their individual clinical situation and be offered an opportunity to consult with a reconstructive plastic surgeon. Breast reconstruction should not interfere with the appropriate surgical management. This may increase the risk of overall and cancer-related death especially in those with late stage disease.\textsuperscript{174} Coordinating consultation and surgical treatment with a reconstructive surgeon should be executed within a reasonable timeframe.

Several reconstructive approaches are summarized for these patients in the NCCN Guidelines for Breast Cancer under Principles of Breast Reconstruction Following Surgery.

The decision regarding type of reconstruction includes patient preference, body habitus, smoking history, comorbidities, plans for irradiation, and expertise and experience of the reconstruction team. Smoking and obesity increase the risk of complications for all types of breast reconstruction whether with implant or flap.\textsuperscript{175-179} Smoking and obesity are therefore considered a relative contraindication to breast reconstruction by the NCCN Panel. Patients should be informed of increased rates of wound healing complications and partial or complete flap failure among smokers and obese patients.

Reconstruction is an optional procedure that does not impact the probability of recurrence or death, but it is associated with an improved quality of life for many patients. It is sometimes necessary to perform surgery on the contralateral breast (i.e., breast reduction, implantation) to achieve optimal symmetry between the ipsilateral reconstructed breast and the contralateral breast.

Breast Reconstruction after Mastectomy
Mastectomy results in loss of the breast for breastfeeding, loss of sensation in the skin of the breast and nipple-areolar complex (NAC), and loss of the breast for cosmetic, body image, and psychosocial purposes. The loss of the breast for cosmetic, body image, and psychosocial issues may be partially overcome through the performance of breast reconstruction with or without reconstruction of the NAC.

Women undergoing mastectomy should be offered consultation regarding options and timing of breast reconstruction.

Many factors must be considered in the decision-making about breast reconstruction. There are several different types of breast reconstruction that include the use of implants, autogenous tissues, or both.\textsuperscript{180-182} Reconstruction with implants can be performed either by immediate placement of a permanent subpectoral implant or initial placement of a subpectoral expander implant followed by gradual expansion of the implant envelope with stretching of the pectoralis major muscle and overlying skin followed by replacement of the expander with a permanent implant. A wide variety of implants are available that contain saline, silicone gel, or a combination of saline and silicone gel inside a solid silicone envelope.

Autogenous tissue methods of reconstruction use various combinations of fat, muscle, skin, and vasculature from donor sites (i.e., abdomen, buttock, back) that may be brought to the chest wall with their original blood supply (pedicle flap) or as free flaps with microvascular anastomoses to supply blood from the chest wall/thorax.\textsuperscript{183} Several procedures using autologous tissue are available including transverse rectus abdominis myocutaneous flap, latissimus dorsi flap, and gluteus maximus myocutaneous flap reconstruction.
Composite reconstruction techniques use implants in combination with autogenous tissue reconstruction to provide volume and symmetry. Patients with underlying diabetes or who smoke tobacco have increased rates of complications following autogenous tissue breast cancer reconstruction, presumably because of underlying microvascular disease.

Reconstruction can be performed either at the time of the mastectomy known as “immediate breast reconstruction” and under the same anesthetic or in a delayed fashion any time, known as “delayed breast reconstruction.” In many cases, breast reconstruction involves a staged approach requiring more than one procedure such as surgery on the contralateral breast to improve symmetry, revision surgery involving the breast and/or donor site, and/or nipple and areola reconstruction and tattoo pigmentation.

Plans for post-mastectomy radiation therapy can impact decisions related to breast reconstruction since there is a significantly increased risk of implant capsular contracture following irradiation of an implant. Furthermore, postmastectomy irradiation may have a negative impact on breast cosmesis when autologous tissue is used in immediate breast reconstruction, and may interfere with the targeted delivery of radiation when immediate reconstruction is performed using either autologous tissue or breast implants. Some studies, however, have not found a significant compromise in reconstruction cosmesis after radiation therapy. The preferred approach to breast reconstruction for irradiated patients was a subject of controversy among the panel. While some experienced breast cancer teams have employed protocols in which immediate reconstruction is followed by radiation therapy, generally radiation therapy is preferred to precede autologous reconstruction due to the reported loss in reconstruction cosmesis (category 2B). When implant reconstruction is planned in a post mastectomy patient requiring radiation therapy, the NCCN Panel prefers a staged approach with immediate tissue expander placement followed by implant placement. Immediate placement of an implant in patients requiring postoperative radiation has an increased rate of capsular contracture, malposition, poor cosmesis, and implant exposure. Surgery to exchange the tissue expanders with permanent implants can be performed prior to radiation or after completion of radiation therapy.

In a previously radiated patient, the use of tissue expanders/implants is relatively contraindicated. Tissue expansion of irradiated skin can result in a significantly increased risk of capsular contracture, malposition, poor cosmesis, implant exposure, and failed reconstruction. If a patient has previously received radiation therapy to the breast, autologous tissue reconstruction is the preferred method of breast reconstruction.

Skin-sparing Mastectomy
Skin-sparing mastectomy procedures are appropriate for some patients and involve removal of the breast parenchyma including the NAC while preserving the majority of the original skin envelope, and are followed by immediate reconstruction with autogenous tissue, a prosthetic implant, or a composite of autogenous tissue and an implant. Skin-sparing mastectomy involving preservation of the skin of the NAC has become the subject of increased attention. Possible advantages of this procedure include improvements in breast cosmesis, body image, and nipple sensation following mastectomy, although the impact of this procedure on these quality-of-life issues has not been well-studied. There are limited data from surgical series, with short follow-up, that suggest that performance of NAC-sparing mastectomy in selected patients is associated with low rates of occult involvement of the NAC with breast cancer and local disease recurrence. NAC-sparing procedures may be an option in patients who are carefully selected by experienced multidisciplinary teams. According to the NCCN Panel, when considering a NAC-sparing procedure, assessment of nipple margins is mandatory.
Retrospective data support the use of NAC-sparing procedures for patients with breast cancer with low rates of nipple involvement and low rates of local recurrence due to early-stage, biologically favorable (i.e., Nottingham grade I or 2, node-negative, HER2-negative, no lymphovascular invasion) invasive cancers and/or DCIS that are peripherally located in the breast (>2 cm from nipple). Contraindications for nipple preservation include evidence of nipple involvement such as Paget’s disease or other nipple discharge associated with malignancy and/or imaging findings suggesting malignant involvement of nipple and subareolar tissues. Several prospective trials are underway to evaluate NAC-sparing mastectomy in the setting of cancer and enrollment in such trials is encouraged.

Advantages of a skin-sparing mastectomy procedure include an improved cosmetic outcome resulting in a reduction in the size of the mastectomy scar and a more natural breast shape, especially when autologous tissue is used in reconstruction, and the ability to perform immediate reconstruction. Although no randomized studies have been performed, results of several mostly retrospective studies have indicated that the risk of local recurrence is not increased when patients receiving skin-sparing mastectomies are compared with those undergoing non-skin-sparing procedures. However, strong selection biases almost certainly exist in the identification of patients appropriate for skin-sparing procedures. Reconstruction of the NAC may also be performed in a delayed fashion if desired by the patient. Reconstructed nipples are devoid of sensation. According to the NCCN Panel, skin-sparing mastectomy should be performed by an experienced breast surgery team that works in a coordinated, multidisciplinary fashion to guide proper patient selection for skin-sparing mastectomy, determine optimal sequencing of the reconstructive procedure(s) in relation to adjuvant therapies, and perform a resection that achieves appropriate surgical margins. Post-mastectomy radiation should still be applied for patients treated by skin-sparing mastectomy following the same selection criteria as for standard mastectomy.

**Breast Reconstruction after Lumpectomy**
Issues related to breast reconstruction also pertain to women who undergo or have undergone a lumpectomy, particularly in situations where the surgical defect is large and/or expected to be cosmetically unsatisfactory. An evaluation of the likely cosmetic outcome of lumpectomy should be performed prior to surgery. Oncoplastic techniques for breast conservation can extend breast-conserving surgical options in situations where the resection by itself would likely yield an unacceptable cosmetic outcome. The evolving field of oncoplastic surgery includes the use of “volume displacement” techniques performed in conjunction with a large partial mastectomy. Oncoplastic volume displacement procedures combine the removal of generous regions of breast tissue (typically designed to conform to the segmentally distributed cancer in the breast) with “mastopexy” techniques in which remaining breast tissues are shifted together within the breast envelope to fill the resulting surgical defect and thereby avoid the creation of significant breast deformity.

Volume displacement techniques are generally performed during the same operative setting as the breast-conserving lumpectomy by the same surgeon who is performing the cancer resection. Advantages of oncoplastic volume displacement techniques are that they permit the removal of larger regions of breast tissue, thereby achieving wider surgical margins around the cancer, and at the same time better preserve the natural shape and appearance of the breast than do standard breast resections.

Limitations of oncoplastic volume displacement techniques include lack of standardization among centers, performance at only a limited number of sites in the United States, and the possible necessity for subsequent mastectomy if pathologic margins are positive when further
breast-conserving attempts are deemed impractical or unrealistic. Nevertheless, the consensus of the panel is that these issues should be considered prior to surgery for women who are likely to have a surgical defect that is cosmetically unsatisfactory, and that women who undergo lumpectomy and are dissatisfied with the cosmetic outcome after treatment should be offered a consultation with a plastic surgeon to address the repair of resulting breast defects. Patients should be informed of the possibility of positive margins and potential need for secondary surgery, which could include re-excision segmental resection, or could require mastectomy with or without loss of the nipple. Oncoplastic procedures can be combined with surgery on the contralateral unaffected breast to minimize long-term asymmetry.

Finally, decisions regarding breast reconstruction should primarily focus should on treatment of the tumor, and such treatment should not be compromised.
Systemic Therapies (Preoperative and Adjuvant)

Systemic Therapy Options

Chemotherapy: A number of chemotherapy regimens have activity in the preoperative setting. According to the NCCN Panel, those regimens recommended in the adjuvant setting may be considered in the preoperative setting. In both settings, the underlying aim remains the same: eradication or control of undiscovered distant metastases.

Endocrine Therapy: Neoadjuvant endocrine therapy alone may be offered to those with strongly HR-positive tumors. According to the NCCN Panel, the endocrine therapy options include an aromatase inhibitor (with ovarian suppression for premenopausal women) or tamoxifen. The preferred endocrine therapy option for postmenopausal women is an aromatase inhibitor.

HER2 Targeted Therapy: For patients with HER2-positive breast cancer, that are candidates for preoperative systemic therapy, chemotherapy and trastuzumab-based therapy is recommended. Chemotherapy and dual anti-HER2 blockade associated with trastuzumab plus pertuzumab has shown significant improvements in the pCR rate when compared with chemotherapy and one anti-HER2 agent in the preoperative setting. In the Neosphere trial, the addition of pertuzumab to trastuzumab and docetaxel preoperatively led to a statistically significant increase in pCR in the breast (16.8% increase; 95% CI, 3.5–30.1; \( P = .0141 \)). In the TRYPHAENA trial, preoperative therapy with pertuzumab and trastuzumab given along with anthracycline-containing or anthracycline-free standard chemotherapy regimens to patients with operable, locally advanced, or inflammatory HER2-positive breast cancer showed pCR rates in all treatment arms ranging from 57% to 66%. The mean change in left ventricular ejection fraction was similar in all treatment arms. The NCCN Panel supports the FDA-approved indication that a pertuzumab-containing regimen may be administered preoperatively to patients with greater than or equal to T2, or greater than or equal to N1, HER2-positive, early-stage breast cancer.

Preoperative Systemic therapy

Principles of Preoperative Systemic Therapy

The NCCN Panel has outlined the rationale, appropriate patient selection, and response assessment for preoperative systemic therapy in a new section titled, Principles of Preoperative Chemotherapy.

Rationale for Preoperative Chemotherapy

Randomized clinical trials have found no significant differences in long-term outcomes when systemic chemotherapy is given before or after surgery. Historically, a primary advantage of administering preoperative systemic therapy has been to improve surgical outcomes. Preoperative systemic therapy can render inoperable tumors resectable and also downstage patients with operable breast cancer desiring breast conservation. Results from large clinical trials and retrospective reviews indicate that breast conservation rates are improved with preoperative systemic therapy. Clinicians need to carefully consider the extent of disease in the breast and likelihood of adequate tumor response before recommending preoperative systemic therapy to improve the likelihood of successful breast conservation.

In addition, use of preoperative systemic therapy may provide important prognostic information based on response to therapy. Achieving a pathologic complete response (pCR) to neoadjuvant therapy is associated with favorable disease-free and OS in early-stage breast cancer. The correlation between pathologic response and long-term outcomes in patients with early-stage breast cancer is strongest for patients with triple-negative breast cancer, less so for HER2-positive disease, and least for hormone-positive disease.
Other benefits of preoperative systemic therapy include allowing time for appropriate genetic testing and for planning breast reconstruction in patients proceeding with mastectomy. For those with significant residual disease after standard preoperative systemic therapy, it may provide an opportunity to identify patients who are candidates for clinical trials of novel agents in the adjuvant setting. To date, the tailoring of therapy based on poor response to standard preoperative chemotherapy has not yet demonstrated improved outcomes. In addition, preoperative systemic therapy also serves as an excellent research platform to test novel therapies and predictive biomarkers by providing tumor specimens and blood samples prior to and during systemic treatment.

Selection of Patients for Preoperative Therapy

Not all patients are appropriate candidates for preoperative systemic therapy. According to the NCCN Panel, among those with inoperable breast tumors, preoperative systemic therapy is indicated in women with locally advanced or inoperable breast cancer including those with inflammatory breast cancer; those with N2 and N3 regional lymph node nodal disease; and T4 tumors. In patients with operable breast cancer who are clear candidates for adjuvant chemotherapy, preoperative systemic therapy may be considered if a patient desires breast-conserving surgery but the surgery is not possible due to the size of the tumor relative to that of the breast, with the hope that this will help obtain clear surgical margins at final resection. Preoperative systemic therapy may also be administered in patients with operable tumors if the patient’s breast cancer subtype is one associated with a high likelihood of response. When preoperative systemic therapy is used to improve the likelihood of successful breast conservation, the surgical plan should consider the possibility that clear surgical margins may not always be obtained, and a follow-up mastectomy may be required, with or without breast reconstruction. This consideration is especially important when oncoplastic breast reduction techniques or contralateral breast symmetry procedures are added to the breast-conserving surgery to achieve optimal cosmetic outcomes.

The NCCN Panel cautions that preoperative systemic therapy is not appropriate for certain patients. Preoperative systemic therapy should not be offered in patients with extensive in situ disease when the extent of invasive disease cannot be defined; in patients where the extent of the tumor is poorly delineated; or in those whose tumors are not palpable or clinically assessable. The decision to utilize preoperative therapy should be made in the context of a coordinated and collaborative multi-disciplinary team.

Response Assessment During Preoperative Chemotherapy

The NCCN panel recommends that tumor response should be routinely assessed by clinical exam during the delivery of preoperative systemic therapy. Patients with operable breast cancer experiencing progression of disease while undergoing preoperative systemic therapy should be taken promptly to surgery. Imaging during preoperative systemic therapy should not be done routinely, but may be considered if tumor progression is suspected. Imaging prior to surgery should be determined by a multi-disciplinary team.
Adjuvant Systemic Therapy

After surgical treatment, adjuvant systemic therapy should be considered. In patients with early-stage breast cancer, systemic adjuvant therapy is administered to reduce risk of cancer recurrence. The decision is often based on individual risk of relapse and predicted sensitivity to a particular treatment (eg, ER/PR and HER2 status). The decision to use systemic adjuvant therapy requires considering and balancing risk for disease recurrence with local therapy alone, the magnitude of benefit from applying adjuvant therapy, toxicity of the therapy, and comorbidity. The decision-making process requires collaboration between the health care team and patient.

Stratification for Systemic Adjuvant Therapy

The NCCN Guidelines stratify patients with breast cancer based on their HR- status and HER2 expression. Patients are then further stratified based on risk of disease recurrence based on anatomic and pathologic characteristics (ie, tumor grade, tumor size, ALN status, angiolymphatic invasion).

Estimating Risk of Relapse or Death and Benefits of Systemic Treatment

Several prognostic factors predict for future recurrence or death from breast cancer. The strongest prognostic factors are patient age, comorbidity, tumor size, tumor grade, number of involved ALNs, and possibly HER2 tumor status. Algorithms have been published estimating rates of recurrence, and a validated, computer-based model (Adjuvant! Online; www.adjuvantonline.com) is available to estimate 10-year DFS and OS that incorporates all of the above prognostic factors except for HER2 tumor status. These tools aid the clinician in objectively estimating outcome with local treatment only, and also assist in estimating the absolute benefits expected from systemic adjuvant endocrine therapy and chemotherapy. These estimates may be utilized by the clinician and patient in their shared decision-making regarding the toxicities and benefits of systemic adjuvant therapy.

Adjuvant Systemic therapy for hormone receptor-positive, HER2-negative tumors

Women with HR positive, HER2-negative tumors, receive adjuvant endocrine therapy to reduce the risk of recurrence and those deemed at high risk for distant recurrence despite adjuvant endocrine therapy, receive adjuvant chemotherapy. The incremental benefit of adding adjuvant chemotherapy to endocrine therapy in patients with low clinical risk of recurrence such as those with very small, low grade, lymph node-negative tumors is relatively small. The decision whether or not to administer adjuvant chemotherapy in patients with HR-positive, HER2-negative tumors is based on many factors including lymph node status, size, grade, lymphovascular invasion, age, comorbid conditions and/or the results of a gene expression profile test using multigene assays.

Multigene Assays

Several commercially-available gene-based assays are useful in determining prognosis by predicting distant recurrence, local recurrence, or survival. Of these, only one, the 21-gene assay (Oncotype DX) has been clinically validated for predicting the benefit of adding adjuvant chemotherapy to further reduce the risk of recurrence.

21-gene assay (Oncotype DX) in Node-negative, HR-positive, HER2-negative disease: The 21-gene recurrence score (RS) is one of the most validated multigene assays. The RS is helpful in determining the prognosis in women with HR-positive, HER2-negative tumors treated with endocrine therapy alone by predicting locoregional and distant recurrence. This assay has also been validated to predict the benefit from adding adjuvant chemotherapy to adjuvant endocrine therapy for
women with HR-positive, HER2-negative, node-negative breast cancer.\textsuperscript{235-237}

Among patients with T1b/c and T2, lymph node-negative, HR-positive, HER2-negative tumors with RS between 0-10, the risk of distant recurrence is low and these patients derive no incremental benefit from the addition of adjuvant chemotherapy to endocrine therapy.\textsuperscript{236,238} At the other end of the spectrum, patients with lymph node-negative, HR-positive, HER2-negative cancers with high RS (≥31) have a higher risk of distant recurrence and secondary analyses of prospective studies demonstrate a clear benefit from adjuvant chemotherapy.\textsuperscript{236,238}

For those with intermediate RS (11-25), the recently reported TAILORx trial of postmenopausal women (n= 6711) with lymph node-negative, HR-positive, HER-2 negative breast cancer, showed similar disease-free survival rates at 9-years in those who received adjuvant chemotherapy followed by endocrine therapy compared with endocrine therapy alone.\textsuperscript{238} However, in a subset analysis, women 50 years of age or younger with RS 16-25 had significantly lower rates of distance recurrence with the addition of adjuvant chemotherapy to endocrine therapy.\textsuperscript{238} The cutoff for low, intermediate, and high RS was different in TAILORx versus NSABP B-20. The NSABP-B20 was the first trial to validate the 21-gene assay both as a prognostic as well as a predictive tool and identified RS cut-offs to predict the magnitude of chemotherapy benefit in patients with node-negative, HR-positive breast cancer.\textsuperscript{7}

21-gene assay (Oncotype DX) in Node- positive, HR-positive, HER2-negative disease: In the West German Plan B study, women (n = 110) with lymph node-positive, HR-positive, HER2-negative tumors, and a RS of ≤11, were found to have a 5-year disease-free survival was 94.4% when treated with endocrine therapy alone.\textsuperscript{239} In a secondary analysis of a prospective registry of women with HR-positive, HER2-negative, lymph node-positive tumors, the 5-year risk of distant recurrence in patients with a RS of <18, treated with endocrine therapy alone was 2.7%.\textsuperscript{240} These results suggest that in patients with limited nodal disease (1-3 positive lymph nodes) and a low RS, the absolute benefit from chemotherapy is likely to be very small.\textsuperscript{240,241}

There is a clear benefit from adjuvant chemotherapy in patients with node positive, HR-positive, HER2-negative tumors, if the RS is high (≥31). In a secondary analysis of the SWOG 8814 trial of women with HR-positive, lymph node-positive tumors, high RS (≥31) was predictive of chemotherapy benefit. This study evaluated breast cancer specimens from node-positive, HR-positive postmenopausal women (n= 367) randomized to endocrine therapy with tamoxifen alone or chemotherapy with CAF followed by tamoxifen.\textsuperscript{235} Compared with tamoxifen alone, treatment with CAF among women with a high RS (≥31) resulted in improved 10-year DFS (55% vs. 43%; HR 0.59, 95% CI 0.35-1.01) and OS (73% vs. 54%; HR 0.56, 95% CI 0.31-1.02).\textsuperscript{235}

The absolute benefit of chemotherapy in patients with limited lymph node involvement and a RS ≤25 remains to be determined. The ongoing Southwest Oncology Group (SWOG) S1007 RxPONDER trial,\textsuperscript{242} assigned women with 1-3 lymph node-positive nodes, HR-positive, HER2-negative breast cancer and a RS ≤ 25 to standard endocrine therapy with or without adjuvant chemotherapy. The results of this trial are expected to determine the benefit (if any) for chemotherapy in this group of patients.

70-gene assay (MammaPrint): Results from the randomized MINDACT trial,\textsuperscript{243} demonstrated that the 70-gene assay can identify a subset of patients who have a low likelihood of distant recurrence despite high-risk clinical features (based on tumor size, grade, nodal status). In this trial, 79% had lymph node-negative disease and 21% had 1-3 positive lymph nodes and all patients underwent risk assessment by clinical criteria (using Adjuvant! Online) and genomic risk assessment by the 70-gene assay.
Patients with low-risk disease according to both clinical criteria and genomic assay results did not receive adjuvant chemotherapy, whereas patients categorized as high-risk by both assessments received chemotherapy. Patients with discordant results (i.e., either high clinical risk/low genomic risk or low clinical risk/high genomic risk) were randomized to the chemotherapy group or the no-chemotherapy group on the basis of either the clinical result or the genomic result. The primary outcome of the study was met with the demonstration that among those with high clinical risk/low genomic risk, the 5-year rate of survival without distant metastasis in those did not receive adjuvant chemotherapy was 94.7% (95% CI, 92.5 to 96.2). In the intention-to-treat population, among patients at high clinical risk/low genomic risk by the 70-gene assay, the 5-year rate of survival with no distant metastasis was 95.9% (95% CI, 94.0 to 97.2) versus 94.4% (95% CI, 92.3 to 95.9) in those who did not receive chemotherapy (adjusted HR for distant metastasis or death with chemotherapy vs. no chemotherapy 0.78; 95% CI, 0.50 to 1.21). Among patients at low clinical risk/ high genomic risk, 5-year survival with no distant metastasis was 95.8% with chemotherapy (95% CI, 92.9 to 97.6), compared with a rate of 95.0% (95% CI, 91.8 to 97.0%) without chemotherapy (adjusted HR for distant metastasis or death with chemotherapy vs. no chemotherapy 1.17; 95% CI, 0.59 to 2.28). These data suggest that the results of the 70-gene signature do not provide evidence for making recommendations regarding chemotherapy for patients at low clinical risk.

In a subgroup analysis by nodal status, among node-negative patients with high clinical risk/low genomic risk, the 5-year rate of survival with no distant metastasis was 95.7% (95% CI, 93.0 to 97.4) in those who received adjuvant chemotherapy compared with 93.2% (95% CI, 90.1 to 95.4) in those who did not receive chemotherapy. Among patients with 1-3 positive lymph nodes, the rates of survival without distant metastases were 96.3% (95% CI, 93.1 to 98.1) in those who received adjuvant chemotherapy versus 95.6% (95% CI, 92.7 to 97.4) in those who did not receive adjuvant chemotherapy. These data suggest that the additional benefit of adjuvant chemotherapy in patients with high-clinical risk/low genomic risk is likely to be small.

50-gene assay (PAM50): The 50-gene assay (PAM-50) risk of recurrence (ROR) score stratifies patients with HR-positive disease into high, medium, and low risk groups. Several studies have demonstrated the prognostic value of ROR score in estimating risk of disease recurrence. In a study from the Danish Breast Cancer Cooperative Group database, patients with lymph node node-negative tumors and low ROR had a distant recurrence risk of 5.0% (95% CI, 2.9% to 8.0%) whereas tumors with high ROR had a distant recurrence risk of 17.8% (95% CI, 14.0% to 22.0%). Based on these analyses, patients with T1 and T2, HR-positive, HER2-negative, lymph node-negative tumors, a ROR score in the low range, regardless of tumor size, places the individual into the same prognostic category as those with T1a–T1b, N0, M0 tumors.

In patients with 1-3 lymph-node positive, HR-positive, HER2-negative disease with low-risk of recurrence score, the distant recurrence risk was less than 3.5% at 10 years with endocrine therapy alone. In TransATAC study, no distant recurrence was seen at 10 years in a similar group.

12-gene assay (EndoPredict): This assay utilizes 12-genes to calculate a prognostic score. This assay appears to be useful in identifying a subgroup of patients with ER-positive, HER2-negative tumors with very low risk of recurrence without adjuvant chemotherapy and helpful in identifying patients at low risk for a late recurrence.
two Austrian Breast Cancer Study Group trials—ABCSG-6 and ABCSG-8, patients with HR-positive, HER-2 negative, and lymph-node node-negative disease with a low-risk score by the 12-gene assay had risk of distant recurrence of 4% at 10 years.\(^{247}\) The prognostic value of the risk score from the 12-gene assay was found to be independent of conventional clinicopathological factors. Patients with T1 and T2 HR-positive, HER2-negative, and lymph node-negative tumors, a 12-gene low-risk score, regardless of T size, places the tumor into the same prognostic category as T1a–T1b, N0, M0.

In TransATAC study, patients with 1-3 positive nodes in the low-risk group had a 5.6% risk of distant recurrence at 10 years,\(^{246}\) suggesting that chemotherapy would be of limited benefit in these women.

**Breast Cancer Index:** The Breast Cancer Index (BCI) is a combination of two profiles, the HOXB13-to-IL17BR expression ratio (H:I ratio) and the Molecular Grade Index (MGI). Compared with clinical prognostic factors (eg, age, tumor size, tumor grade, and lymph node status), the H:I ratio has been shown to be prognostic in the setting of adjuvant tamoxifen monotherapy.\(^{248,249}\) The addition of MGI to H:I was determined to provide additional prognostic discrimination, leading to the BCI assay.\(^{248}\) In a secondary analysis of the ATAC trial, BCI was prognostic in node negative breast cancer for both early (years 0-5) and late (years 5-10) distant recurrence.\(^{250}\) For patients with T1 and T2 HR-positive, HER2-negative, and lymph node-negative tumors, a BCI in the low-risk range, regardless of T size, places the tumor into the same prognostic category as T1a–T1b, N0, M0. There are limited data as to the role of BCI in HR-positive, HER2-negative, and lymph node-positive breast cancer.

**NCCN Recommendations for Use of Multigene Assays:** Considering the ability of the multigene assays to predict benefit of adjuvant systemic chemotherapy and ability to determine prognosis by predicting risk of distant recurrence, the NCCN Panel has summarized the treatment implications based on risk scores and nodal status. The Panel notes that the multigene assays provide prognostic and therapy-predictive information that complements TNM and biomarker information.

**Use of Multigene Assays in Axillary Lymph Node-Negative HR-Positive, HER2-Negative Tumors**

Small tumors (up to 0.5 cm in greatest diameter) that do not involve the lymph nodes have a favorable prognosis so adjuvant chemotherapy is not recommended. According to the NCCN Panel, adjuvant endocrine therapy may be considered in this group of patients to reduce the risk for a second contralateral breast cancer, as well as the small benefit in reducing the risk of local/regional and distant recurrence.\(^{\text{Category 2B}}\).

For patients with invasive ductal or lobular tumors greater than 0.5 cm in diameter and no lymph node involvement (lymph node node-negative), the NCCN panel recommends strongly considering the 21-gene RT-PCR assay to help estimate likelihood of recurrence and benefit from chemotherapy (category 1). The panel has noted that on an exploratory analysis from the TAILORx study,\(^{238}\) adjuvant chemotherapy may be considered in women 50 years of age or younger with a 21-gene RS of 16-25. Also, patients with T1b tumors with low grade histology should be considered for endocrine monotherapy, as the TAILORx study\(^{238}\) did not include patients with such tumors.

The panel notes that other prognostic multigene assays may be considered to help estimate risk of recurrence but these assays have not been validated to predict the benefit of systemic chemotherapy. Also, amongst the other assays, the panel has listed the 70-gene assay as a category 1 option based on the results of the prospective MINDACT\(^{243}\) trial demonstrating the ability of the 70-gene assay to identify a good genomic risk population despite a high clinical risk, in whom chemotherapy may be omitted without a detrimental effect. High clinical risk in the MINDACT trial...
was defined for grade 1 tumors as >3 cm N0 or T2N1, for grade 2 tumors T2N0-1, and for grade 3 tumors T1c-2N0-1.

Furthermore, given no difference in outcomes with or without chemotherapy in the discordant low clinical risk/high genomic risk group, the MINDACT study suggests that the 70-gene panel is not useful guiding systemic chemotherapy decisions in this subgroup of patients.

Since results of different assays may not be concordant with each other and these assays have not been compared head-to-head prospectively, clinicians should only order one of the available assays for a specific patient and tumor.

**Use of Multigene Assays in Axillary Lymph Node-Positive HR-Positive, HER2-Negative Tumors**

For patients with four or more involved nodes the panel recommends systemic adjuvant chemotherapy followed by endocrine therapy (category 1).

Patients with less than four involved nodes or with pN1mi and less than or equal to 2 mm axillary node metastasis, are most often candidates for chemotherapy in addition to endocrine therapy. The panel recommends that clinical decision making for adjuvant chemotherapy be based on elements of clinical risk stratification such as clinical characteristics, tumor stage, pathology and comorbid conditions. If the patient is not a candidate for chemotherapy, the panel recommends adjuvant endocrine therapy alone (category 2A).

For those who are candidates for systemic adjuvant chemotherapy based on clinical characteristics, tumor stage, and pathology, if multigene assay is not available, the panel recommends systemic adjuvant chemotherapy followed by endocrine therapy (category 1).

**Adjuvant Endocrine Therapy**

The NCCN Guidelines call for the determination of ER and PR content in all primary invasive breast cancers. Patients with invasive breast cancers that are ER- or PR-positive should be considered for adjuvant endocrine therapy regardless of patient age, lymph node status, or whether adjuvant chemotherapy is to be administered. Selected studies suggest that HER2-positive breast cancers may be less sensitive to some endocrine therapies, although other studies have failed to confirm this...
A retrospective analysis of tumor blocks collected in the ATAC trial indicated that HER2 amplification is a marker of relative endocrine resistance independent of type of endocrine therapy. However, given the favorable toxicity profile of the available endocrine therapies, the panel recommends the use of adjuvant endocrine therapy in the majority of women with HR-positive breast cancer regardless of menopausal status, age, or HER2 status of the tumor.

**Tamoxifen:** The most firmly established adjuvant endocrine therapy is tamoxifen for both premenopausal and postmenopausal women. In women with ER-positive breast cancer, adjuvant tamoxifen decreases the annual odds of recurrence by 39% and the annual odds of death by 31% irrespective of the use of chemotherapy, patient age, menopausal status, or ALN status. In patients receiving both tamoxifen and chemotherapy, chemotherapy should be given first, followed by sequential tamoxifen. Prospective randomized trials have demonstrated that 5 years of tamoxifen is more effective than 1 to 2 years of tamoxifen.

The ATLAS trial randomly allocated pre- and postmenopausal women to 5 or 10 years (extended therapy) of tamoxifen. The outcome analyses of 6846 women with ER-positive disease showed that by extending adjuvant treatment to 10 years, the risk of relapse and breast cancer-related mortality was reduced. The risk of recurrence during years 5 to 14 was 21.4% for women receiving tamoxifen versus 25.1% for controls (absolute recurrence reduction 3.7%). Patients who received tamoxifen for 10 years had a greater reduction in risk of progression, possibly due to a “carryover effect.” The reduction in risk of recurrence was 0.90 (95% CI, 0.79–1.02) during 5 to 9 years of tamoxifen treatment and 0.75 (0.62–0.90) after 10 years of treatment. There were also decreases in the incidence of contralateral breast cancer. Furthermore, reduced mortality was also apparent after completion of 10 years of treatment with tamoxifen. With regards to toxicity, the most important adverse effects noted in all women in the ATLAS trial after with 10 years of tamoxifen treatment were an increased risk for endometrial cancer and pulmonary embolism. The results of the aTTom trial confirm the significant reduction in recurrence and death from breast cancer seen in the ATLAS trial with 10 versus 5 years of tamoxifen therapy.

In women who are premenopausal at diagnosis, the NCCN Panel recommends tamoxifen treatment with or without ovarian suppression/ablation. Ovarian ablation may be accomplished by surgical oophorectomy or by ovarian irradiation. Ovarian suppression utilizes luteinizing hormone-releasing hormone (LHRH) agonists that result in suppression of luteinizing hormone (LH) and release of follicle-stimulating hormone (FSH) from the pituitary and reduction in ovarian estrogen production. Available LHRH agonists in the United States include goserelin and leuprolide. The EBCTCG performed a meta-analysis of randomized studies of ovarian ablation or suppression alone versus no additional systemic adjuvant therapy for early-stage breast cancer. Analysis of ovarian suppression versus no adjuvant therapy did not demonstrate significant reduction in recurrence (HR 0.72; 95% CI, 0.49–1.04) or death (HR 0.82; 95% CI, 0.47–1.43). In addition, data on ovarian suppression with tamoxifen, chemotherapy, or both showed no significant reduction in reduced recurrence or death.

Studies in premenopausal women of ovarian ablation or suppression alone versus CMF (cyclophosphamide/methotrexate/fluorouracil) chemotherapy alone generally demonstrate similar antitumor efficacy in patients with HR-positive tumors and superior outcomes with CMF in patients with HR-negative tumors. There is also the suggestion that the benefits of ovarian suppression/ablation may be greater in the younger premenopausal group.
Ablation/suppression plus tamoxifen versus chemotherapy alone generally demonstrate no difference in rates of recurrence or survival.\textsuperscript{277-279}

A large intergroup study in premenopausal women with HR-positive, node-positive breast cancer studied adjuvant CAF (cyclophosphamide/doxorubicin/5-fluorouracil) chemotherapy versus CAF plus ovarian suppression with goserelin (CAF-Z) versus CAF-Z plus tamoxifen (CAF-ZT).\textsuperscript{269} The results demonstrated no improvement in time to recurrence or OS comparing CAF with CAF-Z. There was improvement in time to recurrence (HR, 0.73; 95\% CI, 0.59–0.90; \(P < .01\)) but not OS with CAF-Z compared with CAF-ZT (HR, 0.91; 95\% CI, 0.71–1.15; \(P = .21\)). This study did not include a CAF plus tamoxifen arm, so the contribution of the goserelin to the improved time to recurrence in the CAF-ZT arm cannot be assessed. The addition of ovarian suppression/ablation has also been subjected to meta-analysis by the \textit{EBCTCG}.\textsuperscript{277} They identified no statistically significant reduction in annual rates of recurrence or death with the addition of ovarian suppression or ablation to chemotherapy in women less than 40 years or 40 to 49 years of age.

Data from the randomized TEXT–SOFT trials evaluating adjuvant endocrine therapy show that the aromatase inhibitor, exemestane plus ovarian suppression significantly reduces recurrences as compared with tamoxifen.

In two randomized trials (TEXT and SOFT), premenopausal women with HR-positive early-stage breast cancer were assigned to receive exemestane plus ovarian suppression or tamoxifen plus ovarian suppression for a period of 5 years.\textsuperscript{280} Suppression of ovarian estrogen production was achieved with the use of the gonadotropin-releasing hormone agonist triptorelin, oophorectomy, or ovarian irradiation. The DFS was 92.8\% in the exemestane plus ovarian suppression group, as compared with 88.8\% in the tamoxifen plus ovarian suppression group (HR for recurrence, 0.66; 95\% CI, 0.55–0.80; \(P < .001\)).\textsuperscript{280} The OS did not differ significantly between the two groups (HR for death in the exemestane plus ovarian suppression group, 1.14; 95\% CI, 0.86–1.51; \(P = .37\)).\textsuperscript{280} In the SOFT trial,\textsuperscript{281} premenopausal women with hormone-receptor breast cancer were randomized to tamoxifen alone, tamoxifen plus ovarian suppression, or exemestane plus ovarian suppression for 5 years. In the primary analysis, tamoxifen plus ovarian suppression was not superior to tamoxifen alone for DFS. After 67 months of median follow-up, the DFS rate at 5 years was 86.6\% in the tamoxifen–ovarian suppression group and 84.7\% in the tamoxifen alone group (HR 0.83; 95\% CI, 0.66–1.04; \(P = .10\)).\textsuperscript{282} In a subgroup analysis, women at high risk of recurrence, who received prior chemotherapy, had improved outcomes with ovarian suppression. Their chance of remaining disease-free at 5 years was 78\% with tamoxifen alone, 82.5\% with tamoxifen and ovarian suppression, and 85.7\% with exemestane and ovarian suppression.\textsuperscript{282} In the subgroup of women with no prior chemotherapy, no meaningful benefit was seen from ovarian suppression, as women who received tamoxifen alone demonstrated a 95\% chance of remaining disease-free for 5 years.\textsuperscript{281} The OS data from these trials is still pending because the overall follow-up is relatively short in the context of endocrine-sensitive disease.

Based on the results of the SOFT and TEXT trials, the NCCN Panel has included ovarian suppression plus an aromatase inhibitor for 5 years as an adjuvant endocrine therapy option for premenopausal women with hormone-receptor–positive breast cancer at higher risk of recurrence (eg, young age, high-grade tumor, lymph-node involvement).

\textbf{Aromatase inhibitors:} Several studies have evaluated aromatase inhibitors in the treatment of postmenopausal women with early-stage breast cancer. These studies have utilized the aromatase inhibitors as initial adjuvant therapy, as sequential therapy following 2 to 3 years of tamoxifen, or as extended therapy following 4.5 to 6 years of tamoxifen.
The aromatase inhibitors are not active in the treatment of women with functioning ovaries and should not be used in women whose ovarian function cannot reliably be assessed owing to treatment-induced amenorrhea.

The results from two prospective, randomized, clinical trials have provided evidence of an OS benefit for patients with early-stage breast cancer receiving initial endocrine therapy with tamoxifen followed sequentially by anastrozole (HR, 0.53; 95% CI, 0.28–0.99; \( P = .045 \)) or exemestane (HR, 0.83; 95% CI, 0.69–1.00; \( P = .05 \) [excluding patients with ER-negative disease]) when compared with tamoxifen as the only endocrine therapy.283,284 In addition, the NCIC-CTG MA-17 trial demonstrated a survival advantage with extended therapy with letrozole compared with placebo in women with ALN-positive (but not lymph node-negative), ER-positive breast cancer.285 However, no survival differences have been reported for patients receiving initial adjuvant therapy with an aromatase inhibitor versus first-line tamoxifen.286,287 Tamoxifen and aromatase inhibitors have different side effect profiles. Both contribute to hot flashes and night sweats and may cause vaginal dryness. Aromatase inhibitors are more commonly associated with musculoskeletal symptoms, osteoporosis, and increased rate of bone fracture, while tamoxifen is associated with an increased risk for uterine cancer and deep venous thrombosis.

Two studies have examined initial adjuvant endocrine treatment with either tamoxifen or an aromatase inhibitor. The ATAC trial demonstrated that anastrozole is superior to tamoxifen or the combination of tamoxifen and anastrozole in the adjuvant endocrine therapy of postmenopausal women with HR-positive breast cancer.288,289 With a median of 100 months follow-up, results in 5216 postmenopausal women with HR-positive, early-stage breast cancer enrolled in the ATAC trial demonstrated fewer recurrences (HR for DFS, 0.85; 95% CI, 0.76–0.94; \( P = .003 \)) with anastrozole compared with tamoxifen.286 No difference in survival has been observed (HR, 0.90; 95% CI, 0.75–1.07; \( P = .2 \)). Patients in the combined tamoxifen and anastrozole group gained no benefit over those in the tamoxifen group, suggesting a possible deleterious effect from the weak estrogenic effect of tamoxifen in patients with near complete elimination of endogenous estrogen levels.289 ATAC trial sub-protocols show a lesser effect of anastrozole compared with tamoxifen on endometrial tissue,280 similar effects of anastrozole and tamoxifen on quality of life, with most patients reporting that overall quality of life was not significantly impaired,291 a greater loss of bone mineral density with anastrozole,292 a small pharmacokinetic interference of anastrozole in the presence of tamoxifen of unclear significance,293 and no evidence for an interaction between prior chemotherapy and anastrozole.294

BIG 1-98 is a randomized trial testing the use of tamoxifen alone for 5 years, letrozole alone for 5 years, or tamoxifen for 2 years followed sequentially by letrozole for 3 years, or letrozole for 2 years followed sequentially by tamoxifen for 3 years. An early analysis compared tamoxifen alone versus letrozole alone, including those patients in the sequential arms during their first 2 years of treatment only.287 With 8010 women included in the analysis, DFS was superior in the letrozole-treated women (HR, 0.81; 95% CI, 0.70–0.93; log rank \( P = .003 \)). No interaction between PR expression and benefit was observed. No difference in OS was observed. A comparison of the cardiovascular side effects in the tamoxifen and letrozole arms of the BIG 1-98 trial showed that the overall incidence of cardiac adverse events was similar (letrozole, 4.8%; tamoxifen, 4.7%). However, the incidence of grade 3 to 5 cardiac adverse events was significantly higher in the letrozole arm, and both the overall incidence and incidence of grade 3 to 5 thromboembolic events was significantly higher in the tamoxifen arm.295 In addition, a higher incidence of bone fracture was observed for women in the letrozole arm compared with those in the tamoxifen arm (9.5% vs. 6.5%).296 After a longer
follow-up (median 71 months) no significant improvement in DFS was noted with either tamoxifen followed by letrozole or the reverse sequence as compared with letrozole alone (HR for tamoxifen followed by letrozole, 1.05; 99% CI, 0.84–1.32; HR for letrozole followed by tamoxifen, 0.96; 99% CI, 0.76–1.21).297

Five trials have studied the use of tamoxifen for 2 to 3 years followed sequentially by a third-generation aromatase inhibitor versus continued tamoxifen in postmenopausal women. The Italian Tamoxifen Anastrozole (ITA) trial randomized 426 postmenopausal women with breast cancer who had completed 2 to 3 years of tamoxifen to either continue tamoxifen or to switch to anastrozole to complete a total of 5 years of endocrine therapy.298 The HR for relapse strongly favored sequential treatment with anastrozole (HR, 0.35; 95% CI, 0.18–0.68; \( P = .001 \)) with a trend towards fewer deaths (\( P = .10 \)).298 Updated results from this study show the HR for relapse-free survival as 0.56 (95% CI, 0.35–0.89; \( P = .01 \)); P value for OS analysis remained at 0.1.299 The IES trial randomized 4742 postmenopausal women with breast cancer who had completed a total of 2 to 3 years of tamoxifen to either continue tamoxifen or to switch to exemestane to complete a total of 5 years of endocrine therapy.300 The results at a median of 55.7 months of follow-up demonstrated the superiority of sequential exemestane in DFS (HR, 0.76; 95% CI, 0.66–0.88; \( P = .0001 \)) with a significant difference in OS in only patients with ER-positive tumors (HR, 0.83; 95% CI, 0.69–1.00; \( \text{log rank } P = .05 \)). A prospectively planned, combined analysis of 3224 patients enrolled in the ABCSG 8 trial and the ARNO 95 trial has also been reported.301 Patients in this combined analysis had been randomized following 2 years of tamoxifen to complete 5 years of adjuvant tamoxifen or 3 years of anastrozole. With 28 months of median follow-up available, event-free survival was superior with crossover to anastrozole (HR, 0.60; 95% CI, 0.44–0.81; \( P = .0009 \)). No statistically significant difference in survival has been observed. An analysis of the ARNO 95 trial alone after 58 months of median follow-up demonstrated that switching from tamoxifen to anastrozole was associated with significant increases in both DFS (HR, 0.66; 95% CI, 0.44–1.00; \( P = .049 \)) and OS (HR, 0.53; 95% CI, 0.28–0.99; \( P = .045 \)).284 A meta-analysis of ABCSG 8, ARNO 95, and ITA studies showed significant improvement in OS (HR, 0.71; 95% CI, 0.52–0.98; \( P = .04 \)) with a switch to anastrozole.302

The TEAM trial compared treatment of exemestane alone versus sequential therapy of tamoxifen for 2.5 to 3.0 years followed by exemestane to complete 5 years of hormone therapy.303 At the end of 5 years, 85% of patients in the sequential group versus 86% in the exemestane group were disease free (HR, 0.97; 95% CI, 0.88–1.08; \( P = .60 \)). This is consistent with the data from the BIG 1-98 trial,297 in which tamoxifen followed by letrozole or the reverse sequence of letrozole followed by tamoxifen was not associated with significant differences in efficacy versus letrozole monotherapy after a median follow-up of 71 months.

The NCCN panel finds no compelling evidence that there is meaningful efficacy or toxicity differences between the available aromatase inhibitors: anastrozole, letrozole, and exemestane. All three have shown similar anti-tumor efficacy and toxicity profiles in randomized studies in the adjuvant settings.

**Duration of adjuvant endocrine therapy**

Adjuvant endocrine therapy is recommended for a minimum of 5 years. A recent retrospective analysis by the Oxford University studied risk of recurrence for years 5 through 20 after 5 years of endocrine therapy.304 These data showed a considerable risk of recurrence between years 5 and 20 in these patients treated with initial 5 years of endocrine therapy.304 Data has now emerged showing benefit of extended endocrine therapy in improving DFS.
ata from the ATLAS trial (discussed above)\(^2\) and the aTTom trial confirm greater reduction in recurrence and death from breast cancer with 10 versus 5 years of tamoxifen therapy.\(^2\)

For those treated initially with adjuvant tamoxifen, there is evidence for benefit from extended adjuvant endocrine therapy from several randomized trials. Results of the MA-17 trial in 5187 women who had completed 4.5 to 6 years of adjuvant tamoxifen demonstrated that extended therapy with letrozole provides benefit in postmenopausal women with HR-positive, early-stage breast cancer.\(^2\) With a median follow-up of 64 months, letrozole was associated with improved DFS (HR 0.52, 95% CI 0.45-0.61) and an improved OS (HR 0.61, 95% CI 0.52-0.71) compared with placebo.\(^3\)

In a separate cohort analysis of the MA-17 trial, the efficacy of letrozole versus placebo was evaluated after un-blinding of the study in the 1579 women who had been randomly assigned to placebo after 4.5 to 6 years of tamoxifen.\(^2\) The median time since completion of tamoxifen was 2.8 years. Both DFS and distant DFS were significantly improved in the group receiving letrozole, thereby providing some evidence for the efficacy of letrozole in patients who had received 4.5 to 6 years of tamoxifen therapy followed by no endocrine therapy for an extended period. A formal quality-of-life analysis demonstrated reasonable preservation of quality of life during extended endocrine therapy, although women may experience ongoing menopausal symptoms and loss of bone mineral density.\(^2\) No data are available regarding use of aromatase inhibitors for more than 5 years or long-term toxic effects from extended treatment. In addition, the ATLAS trial data do not provide clear direction for treatment of postmenopausal women.\(^2\) There are no data available to suggest that an aromatase inhibitor for 5 years is better for long-term benefit than 10 years of tamoxifen.

In the extension study of ABCSG trial 6, HR-positive postmenopausal patients received 5 years of adjuvant tamoxifen and were randomized to 3 years of anastrozole or no further therapy.\(^2\) At a median follow-up of 62.3 months, women who received anastrozole (n = 387) were reported to have a statistically significantly reduced risk of recurrence compared with women who received no further treatment (n = 469; HR, 0.62; 95% CI, 0.40–0.96; \(P = .031\)).\(^2\)

The differences in design and patient populations among the studies of the aromatase inhibitors do not allow for the direct comparison of the results of these studies. A meta-analysis of adjuvant trials of aromatase inhibitors versus tamoxifen alone versus after 2 or 3 years of tamoxifen documented lower recurrence rates with the aromatase inhibitor-containing regimen, with no clear impact on OS.\(^3\) It is not known whether initial, sequential, or extended use of adjuvant aromatase inhibitors is the optimal strategy.

In women initially treated with an AI, a randomized phase III trial (MA17.R) evaluated the effects of extending adjuvant AI therapy from 5 to 10 years.\(^4\) Postmenopausal women who had completed 4.5 to 6 years of therapy with an AI (with a median duration of prior tamoxifen of 5 years), were randomized to letrozole or placebo for an additional 5 years.\(^4\) Improvement was seen in five-year DFS in those receiving letrozole compared to those who received placebo (95% [95% CI 93 - 96%] vs. 91% [95% CI 89 -93%]). The annual rate of contralateral breast cancer reported was lower with letrozole (0.49% vs. 0.21%; HR 0.42, 95% CI 0.22-0.81%). However, longer duration of AI resulted in more frequent bone-related adverse effects compared with those who received placebo and no improvement was observed with respect to OS. Bone-related adverse effects included bone pain (18% vs. 14%), fractures (14% vs. 9%), and new-onset osteoporosis (11% vs. 6%).\(^4\)
**NCCN Recommendations for Adjuvant Endocrine Therapy for Postmenopausal Women:** The NCCN Guidelines for Breast Cancer recommend the following adjuvant endocrine therapy options for women with early-stage breast cancer who are postmenopausal at diagnosis: an aromatase inhibitor as initial adjuvant therapy for 5 years (category 1); and tamoxifen for 2 to 3 years followed by one of the following options: an aromatase inhibitor to complete 5 years of adjuvant endocrine therapy (category 1) or 5 years of aromatase inhibitor therapy (category 2B); or tamoxifen for 4.5 to 6 years followed by 5 years of an aromatase inhibitor (category 1) or consideration of tamoxifen for up to 10 years. In postmenopausal women, the use of tamoxifen alone for 5 years (category 1) or up to 10 years is limited to those who decline or who have a contraindication to aromatase inhibitors.

**NCCN Recommendations for Adjuvant Endocrine Therapy for Premenopausal Women:** For women premenopausal at diagnosis, the NCCN Guidelines for Breast Cancer recommend 5 years of tamoxifen (category 1) with or without ovarian suppression (category 1) or ovarian suppression plus an aromatase inhibitor for 5 years (category 1). Women who are premenopausal at diagnosis and who become amennorrheic with chemotherapy may have continued estrogen production from the ovaries without menses. Serial assessment of circulating LH, FSH, and estradiol to assure a true postmenopausal status is mandatory if this subset of women is to be considered for therapy with an aromatase inhibitor.315,316

After 5 years of initial endocrine therapy, for women who are postmenopausal at that time (including those who have become postmenopausal during the 5 years of tamoxifen therapy), the NCCN Panel recommends considering extended therapy with an aromatase inhibitor for up to 5 years (category 1) or based on the data from the ATLAS trial considering tamoxifen for an additional 5 years. For those who remain premenopausal after the initial 5 years of tamoxifen, the panel recommends considering continuing up to 10 years of tamoxifen therapy.

**Response to Adjuvant Endocrine Therapy:** The measurement of the nuclear antigen, Ki-67 by IHC, gives an estimate of the tumor cells in the proliferative phase (G1, G2, and M phases) of the cell cycle. Studies have demonstrated the prognostic value of Ki-67 as a biomarker and its usefulness in predicting response and clinical outcome.317 One small study suggests that measurement of Ki-67 after short-term exposure to endocrine treatment may be useful to select patients with tumors resistant to endocrine therapy and those who may benefit from additional interventions.318 However, these data require larger analytic and clinical validation. In addition, standardization of tissue handling and processing is required to improve the reliability and value of Ki-67 testing. At this time, there is no conclusive evidence that Ki-67 alone, especially baseline Ki-67 as an individual biomarker, helps to select the type of endocrine therapy for an individual patient. Therefore, the NCCN Breast Cancer Panel does not currently recommend assessment of Ki-67.

The cytochrome P-450 (CYP450) enzyme, CYP2D6, is involved in the conversion of tamoxifen to endoxifen. Individuals with wild-type CYP2D6 alleles are classified as extensive metabolizers of tamoxifen. Those with one or two variant alleles with either reduced or no activity are designated as intermediate metabolizers and poor metabolizers, respectively. A large retrospective study of 1325 patients found that time to disease recurrence was significantly shortened in poor metabolizers of tamoxifen.319 However, the BIG 1-98 trial reported on the outcome based on CYP2D6 genotype in a subset of postmenopausal patients with endocrine-responsive, early invasive breast cancer.320 The study found no correlation between CYP2D6 allelic status and disease outcome or between CYP2D6 allelic status and tamoxifen-related adverse effects.320 A genetic analysis of the ATAC trial found no association between CYP2D6...
Given the limited and conflicting evidence at this time, the NCCN Breast Cancer Panel does not recommend CYP2D6 testing as a tool to determine the optimal adjuvant endocrine strategy. This recommendation is consistent with the ASCO Guidelines. When prescribing a selective serotonin reuptake inhibitor (SSRI), it is reasonable to avoid potent and intermediate CYP2D6 inhibiting agents, particularly paroxetine and fluoxetine, if an appropriate alternative exists.

Adjuvant bisphosphonate therapy

The antiresorptive agents (bisphosphonates and denosumab) have an established role as preventative and therapeutic agents for the management of osteoporosis, hypercalcemia of malignancy, and bone metastases.

Bisphosphonates: In the Austrian Breast and Colorectal Cancer Study Group trial-12 (ABCSG-12) trial, for patients older than 40 years, zoledronic acid significantly reduced the risk of recurrence by 34% (HR, 0.66; \( P = .014 \)) and the risk of death by 49% (HR, 0.51; \( P = .020 \)). However, no improvement was seen in either DFS or OS in this post hoc analysis among patients younger than 40 years. In a planned subgroup analysis of the AZURE trial, zoledronic acid improved DFS in women who were more than 5 years since menopause at trial entry. A meta-analysis of data from seven adjuvant bisphosphonate trials (AZURE, ABCSG-12, ZO-FAST, Z-FAST, EZO-FAST, NSABP-B34, GAIN), including only those known to be aged 50 years or older, postmenopausal, or with ovarian suppression, showed a significant benefit for the use of adjuvant bisphosphonates in patients with a low-estrogen state and early-stage breast cancer. More recently, the Early Breast Cancer Trials' Collaborative Group (EBTCG) conducted a meta-analysis of all randomized adjuvant bisphosphonate studies (26 studies) and reported convincing evidence that adjuvant bisphosphonates provide benefits to postmenopausal (natural or induced) patients with breast cancer. With bisphosphonate therapy, the greatest improvement was seen in bone recurrence (RR=0.83, \( P = .004 \)) and bone fractures (RR=0.85, \( P = .02 \)). No effect was seen on distant recurrence outside bone (RR =0.98, \( P =0.69 \)). In premenopausal patients, bisphosphonate therapy did not seem to have a significant effect on bone recurrence. However, in postmenopausal patients, zoledronic acid significantly reduced bone recurrence (3.4% vs. 4.5%, RR=0.73, 99% CI 0.53 to 1.00); the difference in breast cancer mortality was not statistically significant (7.1% vs. 7.9%, RR=0.88, 99% CI 0.69 to 1.11).

Denosumab: In the adjuvant setting, the ABCSG-18 trial studied the effect of denosumab in postmenopausal patients treated with adjuvant AIs and showed a reduction in clinical fractures (HR 0.5, \( P < .0001 \)), which was the primary endpoint of this study. Subsequently in an interim analysis, an improvement in DFS, a secondary end point of the trial was reported. However unlike the bisphosphonates which have demonstrated an OS benefit when used as adjuvant therapy, there is no available data showing an OS benefit with denosumab. Results of the ABCSG-18 and the ongoing D-CARE trials may provide evidence for use of denosumab in the adjuvant setting.

NCCN recommendations for use of bisphosphonates as adjuvant therapy: Based on the EBTCG metaanalysis, the panel recommends considering adjuvant bisphosphonate therapy for postmenopausal (natural or induced) women receiving adjuvant endocrine therapy.

Adjuvant Cytotoxic Chemotherapy

Several combination chemotherapy regimens are appropriate to consider when adjuvant cytotoxic chemotherapy is utilized. All adjuvant chemotherapy regimens listed in the NCCN Guidelines have been evaluated in phase III clinical trials, and the current version of the adjuvant
chemotherapy guidelines does not distinguish between options for chemotherapy regimens by ALN status.

The adjuvant chemotherapy guidelines also include specific representative doses and schedules for the recommended adjuvant chemotherapy regimens. The regimens have been categorized as “preferred” or “other.”

The purpose of distinguishing the adjuvant chemotherapy regimens as preferred and other adjuvant chemotherapy regimens is to convey the sense of the panel regarding the relative efficacy and toxicity of the regimens. Factors considered by the panel include the efficacy, toxicity, and treatment schedules of the regimens. Summarized below are clinical trial results focusing on treatment efficacy.

**Preferred Regimens**

Regimens listed as preferred include: dose-dense doxorubicin and cyclophosphamide (AC) with dose-dense sequential paclitaxel; dose-dense AC followed by sequential weekly paclitaxel; and docetaxel plus cyclophosphamide (TC).

The results of two randomized trials comparing AC chemotherapy with or without sequential paclitaxel chemotherapy in women with axillary node-positive breast cancer suggest improved disease-free rates, and results from one of the trials showed an improvement in OS, with the addition of paclitaxel. On retrospective analysis, the apparent advantage of the paclitaxel-containing regimen appears greater in women with ER-negative breast cancers.

A randomized trial evaluated the use of concurrent versus sequential chemotherapy (doxorubicin followed by paclitaxel followed by cyclophosphamide vs. doxorubicin plus cyclophosphamide followed by paclitaxel) given either every 2 weeks with filgrastim support or every 3 weeks. The results show no significant difference between the two chemotherapy regimens, but demonstrate a 26% reduction in hazard of recurrence (\(P = .01\)) and a 31% reduction in the hazard of death (\(P = .013\)) for the dose-dense regimens.

The ECOG E1199 study was a four-arm trial that randomized 4950 women to receive AC chemotherapy followed by either paclitaxel or docetaxel given by either an every-3-week schedule or a weekly schedule. At a median 63.8 months of follow-up, no statistically significant differences in DFS or OS were observed when comparing paclitaxel to docetaxel or weekly versus every-3-week administration. In a secondary series of comparisons, weekly paclitaxel was superior to every-3-week paclitaxel in DFS (HR, 1.27; 95% CI, 1.03–1.57; \(P = .006\)) and OS (HR, 1.32; 95% CI, 1.02–1.72; \(P = .01\)), and every-3-week docetaxel was superior to every-3-week paclitaxel in DFS (HR, 1.23; 95% CI, 1.00–1.52; \(P = .02\)) but not in OS. Based on these results, as well as the findings from the CALGB trial 9741 that showed dose-dense AC followed by paclitaxel every 2 weeks to have a survival benefit when compared with the regimen of AC followed by every-3-week paclitaxel, the every-3-week paclitaxel regimen has been removed from the guidelines.

Combination TC was compared with AC chemotherapy in a trial that randomized 1016 women with stage I to III breast cancer. At a median follow-up of 7 years, overall DFS (81% vs. 75%; HR, 0.74; 95% CI, 0.56–0.98; \(P = .033\)) and OS (87% vs. 82%; HR, 0.69; 95% CI, 0.50–0.97; \(P = .032\)) were significantly improved with TC compared with AC.

**Other Regimens**

Other regimens included in the guidelines are: AC; epirubicin and cyclophosphamide (EC); CMF; AC with sequential docetaxel administered every 3 weeks; AC with sequential weekly paclitaxel; FEC/CEF followed by docetaxel or weekly paclitaxel; FAC followed by weekly paclitaxel; and docetaxel, doxorubicin, and cyclophosphamide (TAC).
The AC regimen for four cycles has been studied in randomized trials, resulting in relapse-free survival and OS equivalent to CMF chemotherapy.339,340 No benefit from dose escalation of either doxorubicin or cyclophosphamide was shown.332,341

Studies of CMF chemotherapy versus no chemotherapy have shown DFS and OS advantages with CMF chemotherapy.47,342 Studies using FAC/CAF chemotherapy have shown that the use of full-dose chemotherapy regimens is important.343 In the EBCTCG overview of polychemotherapy, comparison of anthracycline-containing regimens with CMF showed a 12% further reduction in the annual odds of recurrence ($P = .006$) and an 11% further reduction in the annual odds of death ($P = .02$) with anthracycline-containing regimens.342 Based on these data, the panel qualified the appropriate chemotherapy regimens by the statement that anthracycline-containing regimens are preferred for node-positive patients.

The EBCTCG analysis, however, did not consider the potential interaction between HER2 tumor status and efficacy of anthracycline-containing versus CMF chemotherapy regimens. Retrospective analysis has suggested that the superiority of anthracycline-containing chemotherapy may be limited to the treatment of those breast cancers that are HER2-positive.258,344-349 The retrospective finding across several clinical trials that anthracycline-based chemotherapy may be more efficacious in patients whose tumors are HER2-positive has led to a footnote stating that anthracycline-containing chemotherapy may be superior to non-anthracycline-containing regimens in the adjuvant treatment of such patients.

A trial compared 2 dose levels of EC chemotherapy with CMF chemotherapy in women with node-positive breast cancer.350 This study showed that higher-dose EC chemotherapy was equivalent to CMF chemotherapy and superior to moderate-dose EC in event-free survival and OS.

The NSABP B-36 phase III trial data compared six cycles of 5-fluorouracil, epirubicin, and cyclophosphamide (FEC) with four cycles of AC, both given every 3 weeks as adjuvant therapy in patients with node-negative breast cancer. The rationale for the trial was to determine whether DFS improved with extra cycles of treatments.351 Patient and tumor characteristics were equally distributed between both arms (<50 years of age: 40%, lumpectomy: 68%, and hormone positivity: 65%).351 The results reported that DFS after eight years was not greater for those women who had been on the longer FEC chemotherapy treatment and that the women on the FEC experienced greater side effects. Combined grade 3 and 4 toxicities with a significant difference of 3% or more between AC and FEC arms included fatigue 3.55% versus 8.45%, febrile neutropenia 3.70% versus 9.42%, and thrombocytopenia 0.74% versus 4.41%, respectively.351 Five deaths resulted from the toxicity of FEC treatment, compared to the death of two women on the AC treatment.351

The quality-of-life impact and menstrual history of women on the NSABP (NRG) B-36 was also investigated in a phase III trial.352 Women on FEC treatment experienced a worse quality of life at six months and higher rate of post-chemotherapy amenorrhea.352 Based on the results of the NSABP B-36 trial, the NCCN Panel has now excluded the FEC/CEF and FAC/CAF regimens as options for adjuvant therapy.

Two randomized prospective trials of FEC chemotherapy in ALN-positive breast cancer are available. In one trial, premenopausal women with node-positive breast cancer were randomized to receive classic CMF therapy versus FEC chemotherapy using high-dose epirubicin. Both 10-year relapse-free survival (52% vs. 45%; $P = .007$) and OS (62% vs. 58%; $P = .085$) favored the FEC arm of the trial.353 The second trial compared FEC given intravenously every 3 weeks at 2 dose levels of epirubicin (50 mg/m² vs. 100 mg/m²) in premenopausal and
postmenopausal women with node-positive breast cancer. Five-year DFS (55% vs. 66%; \( P = .03 \)) and OS (65% vs. 76%; \( P = .007 \)) both favored the epirubicin 100 mg/m² arm.\(^{354}\) Another randomized trial in women with ALN-positive breast cancer compared 6 cycles of FEC with 3 cycles of FEC followed by 3 cycles of docetaxel.\(^{278}\) Five-year DFS (78.4% vs. 73.2%; adjusted \( P = .012 \)) and OS (90.7% vs. 86.7%; \( P = .017 \)) were superior with sequential FEC followed by docetaxel. However, no significant DFS differences were seen in a large randomized study comparing adjuvant chemotherapy with 4 cycles of every-3-week FEC followed by 4 cycles of every-3-week docetaxel with standard anthracycline chemotherapy regimens (eg, FEC or epirubicin followed by CMF) in women with node-positive or high-risk, node-negative, operable breast cancer.\(^{355}\)

The addition of weekly paclitaxel after FEC was shown to be superior to FEC alone in a randomized study of 1246 women with early-stage breast cancer.\(^{356}\) The former regimen was associated with a 23% reduction in the risk of relapse compared with FEC (HR, 0.77; 95% CI, 0.62–0.95; \( P = .022 \)), although no significant difference in OS was seen when the two arms were compared at a median follow-up of 66 months.

The phase III E1199 trial compared patients with node-positive or high-risk node-negative breast cancer who received 4 cycles of AC every 3 weeks, followed by either paclitaxel or docetaxel, either weekly or every 3 weeks. The 10-year updated results of this trial showed that incorporation of weekly paclitaxel and docetaxel every 3 weeks was associated with significant improvements in DFS, and marginal improvements in OS, compared with paclitaxel given every 3 weeks. Among patients with triple-negative disease, the 10-year DFS rate with weekly paclitaxel was 69% and the 10-year OS rate was 75%.\(^{357}\)

Final results from a randomized trial of TAC versus FAC chemotherapy in ALN-positive breast cancer demonstrated that TAC is superior to FAC.\(^{358}\) Estimated 5-year DFS was 75% with TAC and 68% with FAC (HR, 0.72; 95% CI, 0.59–0.88; \( P = .001 \)); survival was 87% with TAC and 81% with FAC (HR, 0.70; 95% CI, 0.53–0.91; \( P = .008 \)). DFS favored TAC in both ER-positive and ER-negative tumors. At a median follow-up of 73 months, results from the 3-arm randomized NSABP B-30 trial comparing TAC versus AT versus AC followed by docetaxel (AC followed by T) demonstrated that AC followed by T had a significant advantage in DFS (HR, 0.83; \( P = .006 \)) but not in OS (HR, 0.86; \( P = .086 \)) when compared with TAC. In addition, both DFS (HR, 0.080; \( P = .001 \)) and OS (HR, 0.83; \( P = .034 \)) were significantly increased when AC followed by T was compared with AT, with AT demonstrating non-inferiority compared with TAC.\(^{359}\)

Several retrospective studies have evaluated the potential interaction of chemotherapy benefit and ER status.\(^{47,231}\) These studies assessed the effect of chemotherapy on the risk of breast cancer recurrence in patients with ER-positive tumors receiving adjuvant endocrine therapy when compared with patients with ER-negative tumor status not undergoing adjuvant endocrine therapy. These analyses suggest that the benefits of chemotherapy are significantly greater in patients with ER-negative disease. For example, the results of Berry et al demonstrated that 22.8% more patients with ER-negative tumors survived without disease for 5 years if they received chemotherapy; this benefit was only 7% for patients with ER-positive tumors receiving chemotherapy.\(^{231}\)

For women greater than 70 years of age, the consensus of the panel is that there are insufficient data to make definitive chemotherapy recommendations. Although AC or CMF has been shown to be superior to capecitabine in a randomized trial of women aged greater than or equal to 65 years with early-stage breast cancer,\(^{360}\) the enrollment in that study was discontinued early.\(^{360}\) Therefore, there is also a possibility that AC/CMF is not superior to any chemotherapy in this cohort. The panel
recommends that treatment should be individualized for women in this age group, with consideration given to comorbid conditions.

**Adjuvant HER2-Targeted Therapy**

The panel recommends HER2-targeted therapy in patients with HER2-positive tumors (see *Principles of HER2 Testing* in the NCCN Guidelines for Breast Cancer). Trastuzumab is a humanized monoclonal antibody with specificity for the extracellular domain of HER2. Results of several randomized trials testing trastuzumab as adjuvant therapy have been reported.

NSABP B-31 patients with HER2-positive, node-positive breast cancer were randomly assigned to 4 cycles of AC every 3 weeks followed by paclitaxel for 4 cycles every 3 weeks or the same regimen with 52 weeks of trastuzumab commencing with paclitaxel. In the NCCTG N9831 trial, patients with HER2-positive breast cancer that was node-positive, or node-negative, with primary tumors greater than 1 cm in size if ER- and PR-negative or greater than 2 cm in size if ER- or PR-positive, were similarly randomized except that paclitaxel was given by a low-dose weekly schedule for 12 weeks and a third arm delayed trastuzumab until the completion of paclitaxel.

The B-31 and NCCTG N9831 trials have been jointly analyzed with the merged control arms for both trials compared with the merged arms using trastuzumab begun concurrently with paclitaxel. There were 4045 patients included in the joint analysis performed at 3.9 years median follow-up. A 48% reduction in the risk of recurrence (HR, 0.52; 95% CI, 0.45–0.60; \( P < .001 \)) and a 39% reduction in the risk of death (HR, 0.61; 95% CI, 0.50–0.75; log-rank \( P = .001 \)) were documented. Similar significant effects on DFS were observed when results of the NSABP B-31 and NCCTG N9831 trials were analyzed separately. Cardiac toxicity was increased in patients treated with trastuzumab. In the adjuvant trastuzumab trials, the rates of grade III/IV congestive heart failure (CHF) or cardiac-related death in patients receiving treatment regimens containing trastuzumab ranged from 0% (FinHer trial) to 4.1% (NSABP B-31 trial). The frequency of cardiac dysfunction appears to be related to both age and baseline left ventricular ejection fraction. An analysis of data from N9831 showed the 3-year cumulative incidence of CHF or cardiac death to be 0.3%, 2.8%, and 3.3% in the arms of the trial without trastuzumab, with trastuzumab following chemotherapy, and with trastuzumab initially combined with paclitaxel, respectively. The acceptable rate of significant cardiac toxicity observed in the trastuzumab adjuvant trials in part reflects rigorous monitoring for cardiac dysfunction. Furthermore, concerns have been raised regarding the long-term cardiac risks associated with trastuzumab therapy based on results of follow-up evaluations of cardiac function in patients enrolled in some of these trials.

A third trial (HERA) (N = 5081) tested trastuzumab for 1 or 2 years compared to none following all local therapy and a variety of standard chemotherapy regimens in patients with node-positive disease or node-negative disease with tumor greater than or equal to 1 cm. At a median follow-up of one year, a 46% reduction in the risk of recurrence was reported in those who received trastuzumab compared with those who did not (HR, 0.54; 95% CI, 0.43–0.67; \( P < .0001 \)), there was no difference in OS, and acceptable cardiac toxicity was reported. The 2-year data indicate that 1 year of trastuzumab therapy is associated with an OS benefit when compared with observation (HR for risk of death = 0.66; 95% CI, 0.47–0.91; \( P = .0115 \)). After this initial analysis, patients randomized to chemotherapy alone were allowed to cross over to receive trastuzumab. Intent-to-treat analysis including a crossover patient was reported at 4-year median follow-up. The primary endpoint of DFS continued to be significantly higher in the trastuzumab-treated group (78.6%) versus the observation group (72.2; HR, 0.76; 95% CI, 0.66–0.87; \( P < .0001 \)). At a median follow-up of 8 years, the study reported no significant difference in DFS, a secondary endpoint, in patients treated with trastuzumab for 2
Therefore, 1 year of adjuvant trastuzumab remains the current standard of treatment.

The BCIRG 006 study randomized 3222 women with HER2-positive, node-positive, or high-risk node-negative breast cancer to AC followed by docetaxel; AC followed by docetaxel plus trastuzumab for one year; or carboplatin, docetaxel, and trastuzumab for one year. At 65-month follow-up, patients receiving AC followed by docetaxel with trastuzumab (AC-TH) had an HR for DFS of 0.64 ($P < .001$) when compared with the group of patients in the control arm receiving the same chemotherapy regimen without trastuzumab (AC-T). The HR for DFS was 0.75 ($P = .04$) when patients in the carboplatin/docetaxel/trastuzumab (TCH)-containing arm were compared to patients in the control arm. No statistically significant difference in the HR for DFS was observed between the two trastuzumab-containing arms. An OS advantage was reported for patients in both trastuzumab-containing arms relative to the control arm (HR for AC-TH vs. AC-T = 0.63; $P = .001$; HR for TCH vs. AC-T = 0.77; $P = .04$). Cardiac toxicity was significantly lower in the TCH arm (9.4% patients with >10% relative decline in left ventricular ejection fraction) compared with the AC-TH arm (18.6%; $P < .0001$). CHF was also more frequent with AC-TH than TCH (2% vs. 0.4%; $P < .001$). Analysis of this trial by critical clinical event revealed more distant breast cancer recurrences with TCH (144 vs. 124) but fewer cardiac events with TCH compared with AC-TH (4 vs. 21). In the FinHer trial, 1010 women were randomized to 9 weeks of vinorelbine followed by 3 cycles of FEC chemotherapy versus docetaxel for 3 cycles followed by 3 cycles of FEC chemotherapy. Patients (n = 232) with HER2-positive cancers that were either node-positive or node-negative and greater than or equal to 2 cm and PR-negative were further randomized to receive or not receive trastuzumab for 9 weeks during the vinorelbine or docetaxel portions of the chemotherapy only. With a median follow-up of 3 years, the addition of trastuzumab was associated with a reduction in risk of recurrence (HR, 0.42; 95% CI, 0.21–0.83; $P = .01$). No statistically significant differences in OS (HR, 0.41; 95% CI, 0.16–1.08; $P = .07$) or cardiac toxicity were observed with the addition of trastuzumab. At 5-year follow-up, a comparison of the two arms (ie, chemotherapy with and without trastuzumab) demonstrated that the HRs for distant DFS (HR, 0.65; 95% CI, 0.38–1.12; $P = .12$) and OS (HR, 0.55; 95% CI, 0.27–1.11; $P = .094$) were higher relative to those reported at 3 years.

All of the adjuvant trials of trastuzumab have demonstrated clinically significant improvements in DFS, and the combined analysis from the NSABP B31 and NCCTG N9831 trials, and the HERA trial, showed significant improvement in OS with the use of trastuzumab in patients with high-risk, HER2-positive breast cancer. Therefore, regimens from each of these trials are included as trastuzumab-containing adjuvant regimen choices in the guideline. The benefits of trastuzumab are independent of ER status. In the FNCLCC-PACS-04 trial, 528 women with HER2-positive, node-positive breast cancer were randomly assigned to receive trastuzumab or observation after completion of adjuvant anthracycline-based chemotherapy with or without docetaxel. No statistically significant DFS or OS benefit was observed with the addition of trastuzumab. These results suggest that the sequential administration of trastuzumab following chemotherapy is not as efficacious as a schedule involving concomitant chemotherapy and trastuzumab. The NCCN Guidelines recommend a total of 12 months of adjuvant trastuzumab as the standard of care. Shorter than 12-month duration has not been found to be as effective and longer than 12 months duration does not have any added benefit; it has been found to be as effective as the 12 months of trastuzumab therapy.

Retrospective analyses of low-risk patients with small tumors demonstrate that in T1a-bN0 breast cancers, HER2 overexpression added a 15% to
30% risk for recurrence. These risks rates are substantially higher than seen among similarly sized HER2-negative tumors.

A recent single-arm, multicenter trial studied the benefit of trastuzumab-based chemotherapy in patients with HER2-positive, node-negative tumors less than or equal to 3 cm. All patients received trastuzumab and weekly paclitaxel for 12 weeks, followed by completion of a year of trastuzumab monotherapy. Fifty percent of patients enrolled had tumors less than or equal to 1.0 cm and 9% of patients had tumors that were between 2 and 3 cm. The endpoint of the study was DFS. The results presented at the 2013 Annual San Antonio Breast Cancer Symposium demonstrated that the 3-year DFS rate in the overall population was 98.7% (95% CI, 97.6–99.8; \( P < .0001 \)).

Dual anti-HER2 blockade associated with trastuzumab plus lapatinib and trastuzumab plus pertuzumab has shown significant improvements in the pCR rate when compared with chemotherapy associated with one anti-HER2 agent in the neoadjuvant setting.

However, in the adjuvant setting, the results of the ALTTO trial failed to demonstrate a significant improvement in DFS with dual anti-HER2 therapy compared with trastuzumab alone. After a median follow-up of 4.5 years, the DFS rates were 86% for patients who received trastuzumab alone; 88% for participants treated with trastuzumab and lapatinib concurrently; and 87% for patients who received trastuzumab followed by lapatinib.

**NCCN Recommendation for Adjuvant HER2-Targeted Therapy**

Based on these studies, the panel has designated use of trastuzumab with chemotherapy as a category 1 recommendation in patients with HER2-positive tumors greater than 1 cm.

The NCCN Panel suggests trastuzumab and chemotherapy be used for women with HER2-positive, node-negative tumors measuring 0.6 to 1.0 cm (ie, T1b) and for smaller tumors that have less than or equal to 2 mm axillary node metastases (pN1mi). Some support for this recommendation comes from studies showing a higher risk of recurrence for patients with HER2-positive, node-negative tumors less than or equal to 1 cm compared to those with HER2-negative tumors of the same size. Ten-year breast cancer-specific survival and 10-year recurrence-free survival were 85% and 75%, respectively, in women with tumors characterized as HER2-positive, ER-positive tumors, and 70% and 61%, respectively, in women with HER2-positive, ER-negative tumors. Two more retrospective studies have also investigated recurrence-free survival in this patient population. None of the patients in these two retrospective studies received trastuzumab. In the first study, 5-year recurrence-free survival rates of 77.1% and 93.7% (\( P < .001 \)) were observed for patients with HER2-positive and HER2-negative T1a-bN0M0 breast tumors, respectively, with no recurrence-free survival differences seen in the HER2-positive group when hormonal receptor status was considered. In the other retrospective study of women with small HER2-positive tumors, the risk of recurrence at 5 years was low (99% [95% CI; 96%–100%] for HER2-negative disease and 92% [95% CI; 86%–99%] for HER2-positive disease).

Subgroup analyses from several of the randomized trials have shown consistent benefit of trastuzumab irrespective of tumor size or nodal status.

**NCCN-Recommended HER-Targeted Regimens**

The panel recommends AC followed by paclitaxel with trastuzumab for 1 year commencing with the first dose of paclitaxel as a preferred HER2-targeting adjuvant regimen. The TCH regimen is also a preferred regimen, especially for those with risk factors for cardiac toxicity, given the results of the BCIRG 006 study that demonstrated superior DFS in
patients receiving TCH or AC followed by docetaxel plus trastuzumab compared with AC followed by docetaxel alone.

Other trastuzumab-containing regimens included in the NCCN Guidelines are: AC followed by docetaxel and trastuzumab,368 and docetaxel plus trastuzumab followed by FEC362 (see Preoperative /Adjuvant Systemic Therapy in NCCN Guidelines for Breast Cancer for a complete list of regimens).

Considering the unprecedented improvement in OS in the metastatic setting388 and the significant improvement in pCR seen in the neoadjuvant setting,217,219 the NCCN Panel considers it reasonable to incorporate pertuzumab into the above adjuvant regimens, if the patient did not receive pertuzumab as a part of neoadjuvant therapy. An ongoing study is evaluating pertuzumab and trastuzumab with standard chemotherapy regimens in the adjuvant setting.389,390

The NCCN Panel has included paclitaxel and trastuzumab as an option for patients with low-risk, HER2-positive, stage 1 tumors. This is based on a trial that studied this combination in 406 patients with small, node-negative, HER2-positive tumors. The results showed that the 3-year rate of DFS was 98.7% (95% CI, 97.6–99.8) and the risk of serious toxic effects with this regimen was low (incidence of heart failure reported was 0.5%).391

**Adjuvant Therapy for Tumors of Favorable Histologies**

The guidelines provide systemic treatment recommendations for the favorable histology of invasive breast cancers, such as tubular and mucinous cancers, based on tumor size and ALN status. If used, the treatment options for endocrine therapy, chemotherapy, and sequencing of treatment with other modalities are similar to those of the usual histology of breast cancers. The vast majority of tubular breast cancers are both ER-positive and HER2-negative. Thus, the pathology evaluation and accuracy of the ER and/or HER2 determination should be reviewed if a tubular breast cancer is ER-negative and/or HER2-positive, or if a tumor with an ER- and PR-negative status is grade 1.251 Should a breast cancer be histologically identified as a tubular or mucinous breast cancer and be confirmed as ER-negative, then the tumor should be treated according to the guideline for the usual histology, ER-negative breast cancers. The panel acknowledges that prospective data regarding systemic adjuvant therapy of tubular and mucinous histologies are lacking.

**Staging and Workup Prior to Preoperative Chemotherapy**

The staging evaluation for most patients with stage III invasive breast cancer is similar to the one for patients with T3, N1, M0 disease. The workup includes history and physical exam, a CBC, liver function and alkaline phosphatase tests, chest imaging, pathology review, and pre-chemotherapy determination of tumor ER/PR receptor status and HER2 status. Diagnostic bilateral mammogram and breast ultrasound should be performed as clinically warranted. Genetic counseling is recommended if the patient is considered to be at high risk for hereditary breast cancer as defined by the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

The performance of other studies, such as a breast MRI, a bone scan (category 2B), and abdominal imaging with diagnostic CT (with or without pelvic CT) or MRI (all category 2A) are optional unless directed by symptoms or other abnormal study results. PET/CT scan is also included as an optional additional study (category 2B). Ultrasound is an alternative when diagnostic CT or MRI is unavailable.

The consensus of the panel is that FDG PET/CT is most helpful in situations where standard imaging results are equivocal or suspicious. However, limited studies96,97,392-396 support a potential role for FDG
PET/CT to detect regional node involvement as well as distant metastases in locally advanced breast cancer, including T3, N1, M0 disease.

A retrospective study comparing bone scan with integrated FDG PET/CT, in women with stages I–III breast cancer with suspected metastasis, observed a high concordance (81%) between the two studies for reporting osseous metastases. The NCCN Panel suggests that bone scan may be omitted if FDG PET/CT results are positive for bone metastases.

Equivocal or suspicious sites identified by PET/CT scanning should be biopsied for confirmation whenever possible and if the site of disease would impact the course of treatment. In the past decade, the advent of PET/CT scanners has significantly changed the approach to PET imaging. However, the terminology has also created confusion regarding the nature of the scans obtained from a PET/CT device. PET/CT scanners have both a PET and CT scanner in the same gantry that allows precise coregistration of molecular (PET) and anatomic (CT) imaging. Almost all current clinical PET imaging is performed using combined PET/CT devices.

In PET/CT tomographs, the CT scanner has a second important role beyond diagnostic CT scanning. For PET applications, the CT scan is also used for photon attenuation correction and for anatomic localization of the PET imaging findings. For these tasks, the CT scan is usually taken without breath-holding, to match PET image acquisition, and typically uses low-dose (non-diagnostic) CT. Radiation exposure for these non-diagnostic CT scans is lower than for diagnostic CT. Intravenous contrast is not needed for this task.

PET/CT scanners typically include a high-quality CT device that can also be used for stand-alone, optimized, and fully diagnostic CT. Diagnostic CT scans are acquired using breath-holding for optimal chest imaging, and are often performed with intravenous contrast. For fully diagnostic CT, the CT beam current, and therefore patient radiation exposure, is considerably higher than for the low-dose CT needed for PET requirements. Radiation exposures for fully diagnostic CT are often greater than for the emission (PET) component of the study.

Currently, the approach to clinical PET/CT imaging varies widely across centers. Many centers perform low-dose CT as part of a PET/CT scan, and perform optimized, fully diagnostic CT only when diagnostic CT has also been requested in addition to PET/CT. Other centers combine diagnostic CT scans with PET on all of their PET/CT images. The CT scans described in the workup section of the guidelines refer to fully optimized diagnostic CT scans, while the PET or PET/CT scans refer to scans primarily directed towards the PET component, not necessarily using diagnostic-quality CT. It is important for referring physicians to understand the differences between PET/CT performed primarily for PET imaging and fully optimized CT performed as a stand-alone diagnostic CT examination. It may be convenient to perform PET/CT and diagnostic CT at the same time.

**Operable Locally Advanced Breast Cancer**

Locally advanced breast cancer describes a subset of invasive breast cancer where the initial clinical and radiographic evaluation documents advanced disease confined to the breast and regional lymph nodes. The AJCC clinical staging system used in these guidelines and for the determination of operability is recommended, and locally advanced disease is represented by the stage III category. Patients with stage III disease may be further divided into: 1) those where an initial surgical approach is unlikely to successfully remove all disease or to provide long-term local control; and 2) those with disease where a reasonable initial surgical approach is likely to achieve pathologically negative margins and provide long-term local control. Thus, stage IIIA patients are divided into those who have clinical T3, N1, M0 disease versus those who have
Postsurgical systemic adjuvant therapy for patients with stage II breast cancer who do not receive neoadjuvant chemotherapy is similar to that for patients with stage I disease.

**Inoperable Locally Advanced Breast Cancer**

For patients with inoperable, non-inflammatory, locally advanced disease at presentation, the initial use of anthracycline-based preoperative systemic therapy with or without a taxane is standard therapy. Patients with locally advanced breast cancer that is HER2-positive should receive an initial chemotherapy program that incorporates preoperative trastuzumab and possibly pertuzumab. Local therapy following a clinical response to preoperative systemic therapy usually consists of: 1) total mastectomy with level I/II ALN dissection, with or without delayed breast reconstruction; or 2) lumpectomy and level I/II axillary dissection. Both local treatment groups are considered to have sufficient risk of local recurrence to warrant the use of chest wall (or breast) and supraclavicular node irradiation. If internal mammary lymph nodes are involved, they should also be irradiated. Without detected internal mammary node involvement, consideration may be given to include the internal mammary lymph nodes in the radiation field (category 2B). Adjuvant therapy may involve completion of planned chemotherapy regimen course if not completed preoperatively, followed by endocrine therapy in patients with HR-positive disease. Up to one year of total trastuzumab therapy should be completed if the tumor is HER2-positive (category 1). Endocrine therapy and trastuzumab can be administered concurrently with radiation therapy if indicated.

Patients with an inoperable tumors with disease progression during preoperative systemic therapy should be considered for palliative breast irradiation in an attempt to enhance local control. In all subsets of patients, further systemic adjuvant chemotherapy after local therapy is felt to be standard. Tamoxifen (or an aromatase inhibitor if postmenopausal) should be added for those with HR-positive tumors, and trastuzumab should be given to those with HER2-positive tumors. Post-treatment follow-up for women with stage III disease is the same as for women with early-stage invasive breast cancer.

**Post-Therapy Surveillance and Follow-up for T0-3, N1, M0 and T1-3, N0-1, M0 tumors**

Post-therapy follow-up is optimally performed by members of the treatment team and includes the performance of regular history/physical examinations every 4 to 6 months for the first 5 years after primary therapy and annually thereafter. Mammography should be performed annually.

Regarding frequency of mammograms after breast-conserving surgery followed by radiation, the NCCN Panel agrees with ASTRO’s “Choosing Wisely” list of recommendations released in 2014. The recommendations state that “annual mammograms are the appropriate frequency for surveillance of breast cancer patients who have had breast-conserving surgery and radiation therapy with no clear advantage to shorter interval imaging. Patients should wait 6 to 12 months after the completion of radiation therapy to begin their annual mammogram surveillance. Suspicious findings on physical examination or surveillance imaging might warrant a shorter interval between mammograms.”

The NCCN panel notes that any imaging of reconstructed breast is not indicated.

According to the NCCN Panel, in the absence of clinical signs and symptoms suggestive of recurrent disease, laboratory or imaging studies to screen for metastasis are not necessary. The routine performance of alkaline phosphatase tests and LFTs are not included in the guidelines. In addition, the panel notes no evidence to support the use of “tumor
markers” for breast cancer, and routine bone scans, CT scans, MRI scans, PET scans, or ultrasound examinations in the asymptomatic patient provide no advantage in survival or ability to palliate recurrent disease and are, therefore, not recommended.96,405

The use of breast MRI in follow-up of women with prior breast cancer is undefined. It may be considered as an option in women with high lifetime risk (greater than 20% based on models largely dependent on family history) of developing a second primary breast cancer. Rates of contralateral breast cancer after either breast-conserving therapy or mastectomy have been reported to be increased in women with BRCA1/2 mutations when compared with patients with sporadic breast cancer.406-408

The panel recommends that women with intact uteri who are taking adjuvant tamoxifen should have yearly gynecologic assessments and rapid evaluation of any vaginal spotting that might occur because of the risk of tamoxifen-associated endometrial carcinoma in postmenopausal women.409 The performance of routine endometrial biopsy or ultrasonography in the asymptomatic woman is not recommended. Neither test has demonstrated utility as a screening test in any population of women. The vast majority of women with tamoxifen-associated uterine carcinoma have early vaginal spotting.

If an adjuvant aromatase inhibitor is considered in women with amenorrhea following treatment, baseline levels of estradiol and gonadotropin followed by serial monitoring of these hormones should be performed if endocrine therapy with an aromatase inhibitor is initiated.315 Bilateral oophorectomy assures postmenopausal status in young women with therapy-induced amenorrhea and may be considered prior to initiating therapy with an aromatase inhibitor in a young woman.

Symptom management for women on adjuvant endocrine therapies often requires treatment of hot flashes and the treatment of concurrent depression. Venlafaxine, a serotonin-norepinephrine reuptake inhibitor (SNRI) has been studied and is an effective intervention in decreasing hot flashes.410-413 There is evidence suggesting that concomitant use of tamoxifen with certain SSRIs (eg, paroxetine, fluoxetine) may decrease plasma levels of endoxifen, an active metabolite of tamoxifen.414,415 These SSRIs/SNRIs may interfere with the enzymatic conversion of tamoxifen to endoxifen by inhibiting a particular isoform of CYP2D6. However, the mild CYP2D6 inhibitors such as citalopram, escitalopram, sertraline, and venlafaxine appear to have no or only minimal effect on tamoxifen metabolism.315,416,417

Follow-up also includes assessment of patient adherence to ongoing medication regimens such as endocrine therapies. Predictors of poor adherence to medication include the presence of side effects associated with the medication, and incomplete understanding by the patient of the benefits associated with regular administration of the medication.418 The panel recommends the implementation of simple strategies to enhance patient adherence to endocrine therapy, such as direct questioning of the patient during office visits, as well as brief, clear explanations on the value of taking the medication regularly and the therapeutic importance of longer durations of endocrine therapy.

Lymphedema is a common complication after treatment for breast cancer. Factors associated with increased risk of lymphedema include extent of axillary surgery, axillary radiation, infection, and patient obesity.419,420 The panel recommends educating the patients on lymphedema, monitoring for lymphedema, and referring for lymphedema management as needed.

Many young women treated for breast cancer maintain or regain premenopausal status following treatment for breast cancer. For these women, the NCCN Panel discourages the use of hormonal birth control methods, regardless of the HR status of the tumor.421 Alternative birth

Version 5.2020 © 2020 National Comprehensive Cancer Network® (NCCN®). All rights reserved. NCCN Guidelines® and this illustration may not be reproduced in any form without the express written permission of NCCN.
control methods are recommended, including intrauterine devices, barrier methods, and, for those with no intent of future pregnancy, tubal ligation or vasectomy for the partner. Breastfeeding during endocrine or chemotherapy treatment is not recommended by the NCCN Panel because of risks to the infant. Breastfeeding after breast-conserving treatment for breast cancer is not contraindicated. However, lactation from an irradiated breast may not be possible, or may occur only with a diminished capacity.\textsuperscript{421,422}

The panel recommends that women on an adjuvant aromatase inhibitor or who experience ovarian failure secondary to treatment should have monitoring of bone health with a bone mineral density determination at baseline and periodically thereafter. The use of estrogen, progesterone, or selective ER modulators to treat osteoporosis or osteopenia in women with breast cancer is discouraged. The use of a bisphosphonate is generally the preferred intervention to improve bone mineral density. A single phase 3 study, ABCSG12, demonstrated improved outcomes with the addition of zoledronic acid in premenopausal women receiving endocrine therapy with ovarian suppression.\textsuperscript{423} Use of bisphosphonates in such patients and in other subgroups remains controversial. Denosumab has shown to significantly reduce fractures in postmenopausal women receiving adjuvant therapy aromatase inhibitors, and improves bone mineral density.\textsuperscript{328}

Optimal duration of bisphosphonate therapy has not been established. Factors to consider for duration of anti-osteoporosis therapy include bone mineral density, response to therapy, and risk factors for continued bone loss or fracture. Women treated with a bisphosphonate should undergo a dental examination with preventive dentistry prior to the initiation of therapy, and should take supplemental calcium and vitamin-D.

Evidence suggests that a healthy lifestyle may lead to better breast cancer outcomes. A nested case control study of 369 women with ER-positive tumors who developed a second primary breast cancer compared with 734 matched control patients who did not develop a second primary tumor showed an association between obesity (body mass index [BMI] \(\geq\) 30), smoking, and alcohol consumption and contralateral breast cancer.\textsuperscript{424} A prospective study of 1490 women diagnosed with stage I–III breast cancer showed an association between high fruit and vegetable consumption, physical activity, and improved survivorship, regardless of obesity.\textsuperscript{425} There is emerging evidence that obesity is associated with poorer outcomes for certain subtypes of breast cancers. The study by the Women’s Intervention Nutrition group randomized early-stage breast cancer patients to an intervention group and a control group. The intervention consisted of eight one-on-one visits with a registered dietitian who had been trained on a low-fat eating plan. OS analysis showed no significant difference between the two study arms (17% for the intervention vs. 13.6% without); however, subgroup analysis showed that those with ER- and PR-negative disease who were part of the intervention group saw a 54% improvement in OS.\textsuperscript{426}

The NCCN Panel recommends an active lifestyle and ideal body weight (BMI 20–25) for optimal overall health and breast cancer outcomes as there are reports of proven benefits of exercise and active lifestyle during and after treatment.\textsuperscript{427-429} For management of issues related to survivorship including late/long-term effects of cancer and its treatment, see the NCCN Guidelines for Survivorship.
**Recurrent/Stage IV Breast Cancer**

**Staging and Workup for Recurrent and Stage IV Breast Cancer**

The staging evaluation of women who present with recurrent or stage IV breast cancer includes history and physical exam; the performance of a complete blood count, liver function tests, chest diagnostic CT, bone scan, and radiographs of any long or weight-bearing bones that are painful or appear abnormal on bone scan; diagnostic CT of the abdomen (with or without diagnostic CT of the pelvis) or MRI scan of the abdomen; and biopsy documentation of first recurrence if possible. The NCCN Panel generally discourages the use of sodium fluoride PET or PET/CT scans for the evaluation of patients with recurrent disease. There is limited evidence (mostly from retrospective studies) to support the use of PET/CT scanning to guide treatment planning through determination of the extent of disease in select patients with recurrent or metastatic disease. In general, the non-diagnostic CT scans used for PET under-evaluate the lungs and the liver compared with contrast-enhanced diagnostic CT scans. The panel considers biopsy of equivocal or suspicious sites to be more likely than PET/CT scanning to provide accurate staging information in this population of patients.

The consensus of the NCCN Panel is that FDG PET/CT is optional and most helpful in situations where standard imaging results are equivocal or suspicious. The NCCN Panel recommends bone scan or sodium fluoride PET/CT (category 2B) to detect bone metastases. However, if the FDG PET results clearly indicate bone metastasis, these scans can be omitted.

The NCCN Panel recommends that metastatic disease at presentation or first recurrence of disease should be biopsied as a part of the workup for patients with recurrent or stage IV disease. This ensures accurate determination of metastatic/recurrent disease and tumor histology, and allows for biomarker determination and selection of appropriate treatment.

Soft tissue tumor biopsy is preferred over bone sites unless a portion of the biopsy can be protected from harsh decalcification solution to preserve more accurate assessment of biomarkers.

Determination of HR status (ER and PR) and HER2 status should be repeated in all cases when diagnostic tissue is obtained. ER and PR assays may be falsely negative or falsely positive, and there may be discordance between the primary and metastatic tumors. The reasons for the discordance may relate to change in biology of disease, differential effect of prior treatment on clonal subsets, tumor heterogeneity, or imperfect accuracy and reproducibility of assays. Discordance between the receptor status of primary and recurrent disease has been reported in a number of studies. The discordance rates are in the range of 3.4% to 60% for ER-negative to ER-positive; 7.2% to 31% for ER-positive to ER-negative; and 0.7% to 11% for HER2.

The NCCN Panel recommends that re-testing the receptor status of recurrent disease be performed, especially in cases when it was previously unknown, originally negative, or not overexpressed. For patients with clinical courses consistent with HR–positive breast cancer, or with prior positive HR results, the panel has noted that a course of endocrine therapy is reasonable, regardless of whether the receptor assay is repeated or the result of the most recent HR assay.

Genetic counseling is recommended if the patient is considered to be at high risk for hereditary breast cancer, as defined by the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

Genetic testing: In the metastatic setting, results from genetic testing may have therapeutic implications. Germline mutations in BRCA1/2 have proven clinical utility and therapeutic impact. Therefore, germline BRCA1/2 mutations should be assessed in all patients with recurrent or metastatic
Management of Locally Recurrent Disease

Patients with local recurrence only are divided into 3 groups: those who had been treated initially by mastectomy alone, those who had been treated initially by mastectomy plus radiation therapy, and those who had received breast-conserving therapy plus radiation therapy.

In one retrospective study of local recurrence patterns in women with breast cancer who had undergone mastectomy and adjuvant chemotherapy without radiation therapy, the most common sites of local recurrence were at the chest wall and the supraclavicular lymph nodes. The recommendations for treatment of the population of patients experiencing a local recurrence only are supported by analyses of a combined database of patients from the EORTC 10801 and Danish Breast Cancer Cooperative Group 82TM trials. The analyses compared breast-conserving therapy with mastectomy in patients with stage I and stage II disease. The 133 (approximately 8%) patients experiencing a local recurrence as an initial event were approximately equally divided between those who had undergone mastectomy and those who had received breast-conserving therapy as initial treatment for breast cancer. Of those in the former group, 51 (76%) were able to undergo radiation therapy with or without surgery as treatment for local disease recurrence. No difference in survival emerged between patients receiving treatment after initial treatment with mastectomy or breast-conserving therapy; approximately 50% of both groups were alive at 10-year follow-up.

According to the NCCN Panel, mastectomy-treated patients should undergo surgical resection of the local recurrence (if it can be accomplished with limited morbidity) and involved-field radiation therapy to the chest wall and supraclavicular area (if the chest wall was not previously treated or if additional radiation therapy may be safely administered). The use of surgical resection in this setting implies the use of limited excision of disease with the goal of obtaining clear margins of resection. Unresectable chest wall recurrent disease should be treated with radiation therapy if no prior radiation has been given.

In women with a local breast recurrence after breast-conserving surgery and radiation therapy who had a prior sentinel lymph node (SLN) biopsy, a repeat SLN biopsy may be considered although the accuracy of repeat SNB is unproven, and the prognostic significance of repeat SNB after mastectomy is unknown and its use is discouraged. On the other hand, the prognostic significance of repeat SLN biopsy after mastectomy is unknown and its use is discouraged. The consensus of the panel is that for most women with a local recurrence following breast-conserving therapy and SLN biopsy is mastectomy and a level I/II axillary dissection.

The results of the CALOR trial found that after complete resection in patients with isolated locoregional recurrence, adjuvant chemotherapy improves both DFS and OS. After median follow-up of 4.9 years, the overall DFS was 69% in the chemotherapy group versus 57% in the group that did not receive chemotherapy (HR = 0.59, P = .046). Five-year OS in all patients in the study was also significantly improved with chemotherapy (88% vs. 76%, P = .024). The benefit of adjuvant chemotherapy was mostly seen in women with ER-negative disease. Among women with ER-negative disease, 5-year DFS was 67% versus 35% (HR, 0.32; 95% CI, 0.14–0.73) and in those ER-positive disease, the 5-year DFS was 70% versus 69% (HR, 0.94; 95% CI, 0.47–1.89). However these women received endocrine therapy.

According to the NCCN Panel, after local treatment, women with local recurrences only should be considered for limited duration systemic chemotherapy or endocrine therapy similar to that outlined in the adjuvant chemotherapy section. The panel emphasized the importance of...
individualizing treatment strategies in patients with a recurrence of disease limited to a local site.

Management of Recurrent or Stage IV Disease
From the time of diagnosis of recurrent/stage IV metastatic disease, patients should be offered appropriate supportive care and symptom-related interventions as a routine part of their care. NCCN believes that the best management of any patient with cancer is in a clinical trial. Patients should be encouraged to participate in clinical trials whenever clinical trials are available.

Surgery for Recurrent or Stage IV Disease
The primary treatment approach recommended by the NCCN Panel for women with metastatic breast cancer and an intact primary tumor is systemic therapy, with consideration of surgery after initial systemic treatment for those women requiring palliation of symptoms or with impending complications, such as skin ulceration, bleeding, fungation, and pain. Generally such surgery should be undertaken only if complete local clearance of tumor may be obtained and if other sites of disease are not immediately threatening to life. Alternatively, radiation therapy may be considered as an option to surgery. Often such surgery requires collaboration between the breast surgeon and the reconstructive surgeon to provide optimal cancer control and wound closure.

Retrospective studies suggest a potential survival benefit from complete excision of the in-breast tumor in select patients with metastatic breast cancer. Substantial selection biases exist in all of these studies and are likely to confound the study results.

Two prospective, randomized studies assessed whether or not surgery on the primary tumor in the breast is necessary for women who are diagnosed with metastatic/stage IV breast cancer. In the first prospective trial, women (n =350) with de-novo metastatic breast cancer who achieved a partial or complete response to anthracycline-based chemotherapy were randomly assigned to either surgery of the primary tumor plus adjuvant radiation versus no locoregional treatment. There was no difference in the overall survival (OS) between the group that received surgery and the group that did not (19.2 vs. 20.5 months, hazard ratio [HR] 1.04, 95% CI 0.81-1.34). In a separate multiple center prospective registry study women who responded to first-line systemic therapy were randomized to management of the primary tumor by surgery or not. Preliminary data showed no difference in OS between the two groups.

However, another trial by the Turkish Federation, MF07-01 of women (n=274) with de-novo metastatic breast cancer randomized to local management (mastectomy, or BCS with radiation) followed by systemic therapy versus systemic therapy only, observed a benefit with surgery. While no difference in survival was seen at 36 months, at 40 months, patients treated with local management showed an improvement in survival with locoregional treatment (46.4% vs. 26.4%; HR 0.66, 95% CI 0.49-0.88). The design of this trial is different from the other the first being two prospective studies described above in which patients were included only if they had experienced a response to systemic therapy. Second, randomization in the Turkish trial was not balanced. Patients who received surgery had lower rates of triple-negative disease (7% vs. 17%), visceral metastases (29% vs. 45%), and many had solitary bone metastases only (33% vs. 20%). In an unplanned subgroup analysis, patients who appeared to derive the greatest OS benefit from local management included those with HR-positive disease, (HR 0.63; 95% CI 0.44–0.89; P = .008); HER2-negative disease (HR 0.64; 95% CI 0.45–0.91; P = .01); those younger than 55 years HR 0.57; 95% CI 0.38–0.86; P = .007; and those with solitary bone metastases (HR 0.47; 95% CI 0.23–0.98; P = 0.04).
The panel recognizes the need for more data from randomized clinical trials that will address the risks and benefits of local therapy for patients with stage IV disease while eliminating selection biases. Though the available data does not support broadly considering local therapy with surgery and/or RT, this may be reasonable in select patients responding to initial systemic therapy. In such clinical scenarios, patient engagement in the decision is encouraged.

Guideline Stratification for Systemic Therapy for Stage IV/Recurrent Disease
The systemic treatment of breast cancer recurrence or stage IV disease prolongs survival and enhances quality of life (QOL) but is not curative. Therefore, treatments associated with minimal toxicity are preferred. Thus, the use of the minimally toxic endocrine therapies is preferred to the use of cytotoxic therapy whenever reasonable.460 Guidance for treatment of patients with breast cancer and brain metastases is included the NCCN Guidelines for Central Nervous System.

Patients with recurrent or stage IV breast cancer at diagnosis are initially stratified according to whether bone metastases is present. These two patient subsets (those with and without bony metastases) are then stratified further by tumor HR and HER2 status.

Therapy for Bone Metastases
Complications from bone metastases include pain, decreased performance status, and decreased QOL, as well as skeletal-related events (SREs), which are defined as the need for radiation or surgery to bone, pathologic fractures, spinal cord compression, and hypercalcemia of malignancy.

The NCCN Panel recommends treatment with a bone modifying agent such as zoledronic acid, pamidronate or denosumab (category 1) in addition to chemotherapy or endocrine therapy if bone metastasis is present, expected survival is ≥3 months. Patients should undergo a dental examination with preventive dentistry prior to initiation of this therapy. The bisphosphonates and denosumab are associated with a risk of development of osteonecrosis of the jaw (ONJ). Poor baseline dental health or dental procedures during treatment are known risk factors for ONJ. Thus, a dental examination with preventive dentistry intervention is recommended prior to treatment with intravenous bisphosphonate or denosumab, and dental procedures invasive of gum or bone during treatment should be avoided if at all possible. Additional risk factors for the development of ONJ include administration of chemotherapy or corticosteroids and poor oral hygiene with periodontal disease and dental abscess.461

Bisphosphonates
There are extensive data from randomized trials in support of the use of bisphosphonates for patients with metastatic disease to bone. The randomized clinical trial data include the use of zoledronic acid and pamidronate in the United States and ibandronate and clodronate in European countries.462-469 In metastatic bone disease, bisphosphonate treatment is associated with fewer SREs, fewer pathologic fractures, and less need for radiation therapy and surgery to treat bone pain.

The use of bisphosphonates in metastatic disease is a palliative care measure. No impact on OS has been observed in patients treated with bisphosphonates.

The data indicate that zoledronic acid and pamidronate may be given on a 3- to 4-week schedule in conjunction with antineoplastic therapy (i.e., endocrine therapy, chemotherapy, biologic therapy) or every 12 weeks. Three randomized trials have compared zoledronic acid dosed every 4 weeks versus every 12 weeks.470-472 Data from these trials show that among women with breast cancer and bone metastases zoledronic acid administered once every 12 weeks versus once every four weeks does not
compromise efficacy and has similar rates of SREs. In the ZOOM trial, the rate of skeletal morbidities was 0.22 (95% CI, 0.14 to 0.29) in those receiving zoledronic acid every 4 weeks versus 0.26 (95% CI, 0.15 to 0.37) those receiving zoledronic acid every 12 weeks. In the CALGB 70604 trial, the rate of SRE rate in the 4-week arm was 29.5% versus 28.6% in the 12-week arm. In OPTIMIZE-2 trial, the rate of SREs was 22% of the in the 4-week arm and 23.2% in the 12-week arm. The NCCN Panel recommends an optimal dosing of every 12 weeks.

The use of bisphosphonates should be accompanied by calcium and vitamin D supplementation with daily doses of calcium of 1200 to 1500 mg and vitamin D3 of 400 to 800 IU. Recommended agents for use in the United States are pamidronate 90 mg intravenously over 2 hours or zoledronic acid 4 mg intravenously over 15 minutes. The original studies continued treatment for up to 24 months; however, there are limited long-term safety data indicating treatment can continue beyond that time. The risk of renal toxicity necessitates monitoring of serum creatinine prior to administration of each dose and dose reduction or discontinuation if renal function is reduced. Current clinical trial results support the use of bisphosphonates for up to 2 years. Longer durations of bisphosphonate therapy may provide additional benefit, but this has not yet been tested in clinical trials.

**Denosumab**

Women with metastatic breast cancer to bone who are candidates for bisphosphonate therapy may also be considered for treatment with denosumab. This recommendation is based on the results of a single randomized trial comparing denosumab to zoledronic acid. All trial patients were recommended to supplement with vitamin D and calcium. Patients on the experimental arm were given 120 mg of denosumab injected subcutaneously every 4 weeks plus intravenous placebo versus the control arm where patients were given an intravenous infusion of 4 mg of zoledronic acid every 4 weeks, and a subcutaneous placebo. In this trial with non-inferiority as the primary endpoint, denosumab was shown to significantly delay time to first SRE by 18% as compared with zoledronic acid (HR, 0.82; 95% CI, 0.71–0.95; \( P < .001 \) for non-inferiority; \( P = .01 \) for superiority) and time to first and subsequent SREs (rate ratio, 0.77; 95% CI, 0.66–0.89; \( P = .001 \)). No difference in time to progression or OS was observed. Dosing of denosumab outside of every 3-6 weeks has not been studied.

**Systemic Therapy for Stage IV or Recurrent Metastatic HR-Positive, HER2-Negative Breast Cancer**

Women with Stage IV or recurrent disease characterized by tumors that are HR-positive, HER2-negative tumors with no visceral crisis are treated with endocrine therapy alone or endocrine therapy in combination with targeted agents.

Women whose disease progresses after a year from the end of adjuvant endocrine-based therapy and those who present with de novo Stage IV/metastatic breast cancer are eligible for first-line endocrine therapies. Many premenopausal and postmenopausal women with HR-positive breast cancer benefit from sequential use of endocrine therapies at disease progression. Therefore, women with breast cancers who respond to an endocrine-based therapy with either shrinkage of the tumor or long-term disease stabilization (clinical benefit) should receive additional endocrine therapy at disease progression. Those who progress on or within 12 months of completing adjuvant endocrine or patients who progress on first-line endocrine therapy for metastatic disease are eligible for second-line endocrine therapy either as monotherapy or in combination with a targeted agent. The optimal sequence for endocrine therapy is not well defined. The choice would depend on previous, tolerance of treatment, and patient preference.
Many trials in HR-positive patients have not included premenopausal women. The NCCN Panel that recommends women with HR-positive disease should have adequate ovarian suppression/ablation and then be treated in the same way as post-menopausal women. The NCCN panel has outlined endocrine-based therapies that would be used in the first-line versus second- and subsequent-line settings.

**Preferred First Line therapy for HR- Positive, HER2-Negative Breast Cancer**

**Aromatase inhibitor in combination with CDK 4/6 inhibitor:** In postmenopausal women or premenopausal women receiving ovarian ablation or ovarian function suppression with an LHRH agonist, combinations of aromatase inhibitors (AI) with CDK 4/6 inhibitors (palbociclib, ribociclib, or abemaciclib) have demonstrated improved PFS relative to an AI alone.

Palbociclib in combination with letrozole was studied in a phase III study that included postmenopausal patients (n=666) with metastatic, HR-positive, HER2-negative breast cancer who had not received prior treatment for advanced disease. An improvement in PFS (24.8 vs. 14.5 months; hazard ratio [HR] 0.58, 95% CI 0.46-0.72) and objective response rate (ORR; 42 vs. 35 percent) was seen with the combination of palbociclib and letrozole compared with letrozole alone. Grade 3 and 4 adverse effects seen with the combination of palbociclib and letrozole included neutropenia (66.5% vs. 1.4%), leukopenia (24.8% vs. 0%), anemia (5.4% vs. 1.8%) and fatigue (1.8% vs. 0.5%).

Ribociclib in combination with letrozole was also studied as first-line therapy in a phase III study of postmenopausal women (n=668) with HR-positive, HER2-negative recurrent/Stage IV breast cancer. At a median follow-up of 26.4 months, an improvement in PFS (25.3 vs. 16.0 months; HR for progression or death was 0.56, 95% CI 0.45-0.70) and improved ORR of 43% vs. 29% was seen with ribociclib plus letrozole compared with letrozole alone. Grade 3 or 4 adverse events were more common with the combination included neutropenia (62% vs. 1.2%), leukopenia (21.3% vs. 0.9%), and abnormal liver function tests (10.2% vs. 2.4%).

The phase III MONARCH trial studied the combination of abemaciclib with either an AI (letrozole or anastrozole) versus AI monotherapy as first-line treatment of women with advanced HR-positive, HER2-negative breast cancer. The combination of abemaciclib with the AI improved PFS, compared with AI alone (median not reached versus 14.7 months, respectively; HR 0.54, 95% CI 0.41-0.72). The ORR was higher with the combination compared with AI monotherapy (59% vs. 44%). The most frequent grade 3 or higher adverse events for abemaciclib versus placebo included diarrhea (9.5% vs. 1.2%), neutropenia (21.1% vs. 1.2%), leukopenia (8% vs. 0.6%) and fatigue (2% vs 0%).

Most trials studying CDK 4/6 inhibitor with an AI have mainly included postmenopausal women and only a small subset of premenopausal women on ovarian suppression. However, in the phase III MONALEESA-7 trial, 672 pre- or perimenopausal women with HR-positive, HER2-negative, advanced breast cancer were randomly assigned to first-line treatment with ribociclib or placebo with goserelin plus either a non-steroidal AI or tamoxifen. An improvement in PFS was seen with the addition of ribociclib (median PFS, 24 versus 13 months; HR 0.55, 95% CI 0.4-0.69). At 3.5 years, an improvement in OS was reported with ribociclib (70% vs. 46%; HR 0.71, 95% CI 0.54-0.95). Grade 3 and 4 adverse events reported in greater than 10% of patients in either group included neutropenia (61% vs. 4%) and leukopenia (14% vs. 1%).

Based on the above data, the NCCN panel has included AI in combination with CDK 4/6 inhibitors as a category 1 first-line option for...
postmenopausal women and premenopausal women with ovarian ablation/suppression with HR-positive, HER2-negative recurrent/stage IV breast cancer.

**Single agent fulvestrant:** Fulvestrant is an estrogen receptor (ER) antagonist and was originally approved as a monthly intramuscular injection (250 mg per month); higher dose has been proven to be more effective in subsequent randomized trials. In the first-line setting, fulvestrant was found to be as effective as anastrozole in terms of ORR (36.0% vs. 35.5%; odds ratio, 1.02; 95% CI, 0.56 – 1.87).\(^{481}\) An improved time to progression was seen with fulvestrant compared to anastrozole (median time to progression was 23.4 months for fulvestrant versus 13.1 months for anastrozole; HR, 0.63; 95% CI, 0.39– 1.00; \(P = .0496\)).\(^{482}\) This study also used a higher loading dose of 500 mg every 2 weeks for 3 doses and then maintenance dose of 500 mg monthly.\(^{481}\) The median OS was observed to be longer in the fulvestrant group than in the anastrozole group (54.1 months vs. 48.4 months; HR, 0.70; \(P = .041\)).\(^{483}\)

A separate phase III randomized study in postmenopausal women with metastatic HR-positive breast cancer compared fulvestrant 500 mg every 2 weeks for 3 doses followed by 500 mg monthly versus fulvestrant 250 mg monthly. The PFS was superior with the fulvestrant 500 mg regimen (HR, 0.80; 95% CI, 0.68–0.94; \(P = .006\)).\(^{484}\) indicating an increased duration of response with the higher dose of fulvestrant. The final analyses demonstrated an increase in median OS (4.1 months) and reduced risk of death (19%) with a dose of 500 mg compared with 250 mg. Median OS was 26.4 versus 22.3 months (HR, 0.81; 95% CI, 0.69–0.96; \(P = .02\)).\(^{485}\)

Results from another phase III trial (FALCON) of first-line treatment with fulvestrant compared with anastrozole in endocrine therapy-naive patients with metastatic ER-positive breast cancer, demonstrated improved PFS with fulvestrant (at the higher dose, 500 mg) over anastrozole at a median follow-up of 25.0 months (16.6 vs. 13.8 months, HR for progression or death 0.797, 95% CI 0.637-0.999).\(^{486}\) The QOL outcomes were similar between the two groups, with the most common adverse effects being arthralgia (17% vs. 10%) and hot flashes (11% vs. 10%) for fulvestrant and anastrozole, respectively.\(^{486}\)

**Fulvestrant + CDK 4/6 inhibitor:** In the phase III trial MONALEESA-3, patients (\(n = 726\)) with advanced HR-positive breast cancer who had no prior endocrine therapy or had progressed on prior therapy, the combination of ribociclib with fulvestrant showed improved in PFS versus fulvestrant alone (21 vs. 13 months; HR 0.59, 95% CI 0.48-0.73).\(^{487}\) The PFS benefits were consistent across patients with and without prior endocrine treatment. In a subsequent analysis, a significant improvement in OS was observed.\(^{488}\) At 42 months the estimated OS was 57.8% (95% confidence interval [CI], 52.0 to 63.2) in the ribociclib group and 45.9% (95% CI,36.9 to 54.5) in the placebo group.\(^{488}\)

Comparison across multiple trials, including those in the second-line settings studying combination of fulvestrant with palbociclib or abemaciclib have shown statistically significant improvement in PFS. Based on the results of the Monaleesa-3 trial and extrapolation results from the second-line setting, the NCCN Panel has included fulvestrant in combination with CDK 4/6 inhibitors as a category 1 first-line option for postmenopausal women and premenopausal women with ovarian ablation/suppression with HR-positive, HER2-negative recurrent/stage IV breast cancer.

**Fulvestrant + non-steroidal AI:** Combination of two endocrine agents as first-line treatment in postmenopausal women with HR-positive, metastatic breast cancer has been reported from studies comparing single-agent anastrozole versus anastrozole plus fulvestrant.

In one study (FACT), combination of fulvestrant with anastrozole was not superior to single-agent anastrozole (time to progression HR, 0.99; 95%
In a second phase III trial (SoFEA), the effect of fulvestrant alone or in combination with anastrozole or exemestane was studied in patients with advanced breast cancer with acquired resistance to an non-steroidal AI. An AI had been given as adjuvant treatment to 18% of patients for a median of 27.9 months, and to 82% of patients for locally advanced/metastatic disease for a median of 19.3 months. Median PFS was 4.8 months, 4.4 months, and 3.4 months for patients treated with fulvestrant alone, anastrozole plus fulvestrant, and fulvestrant plus exemestane, respectively. No differences were observed for ORR, clinical benefit rate, and OS.

In the trial by the Southwest Oncology Group (SWOG), S0226, PFS (HR, 0.80; 95% CI, 0.68–0.94; stratified log-rank \( P = .007 \)) and OS (HR, 0.81; 95% CI, 0.65–1.00; stratified \( P = .049 \)) were superior with combination anastrozole plus fulvestrant. In a subgroup analysis in this trial suggested that patients without prior adjuvant tamoxifen experienced the greatest OS benefit with combination therapy compared with monotherapy (median, 52.2 months vs.40.3 months, respectively; hazard ratio, 0.73; 95% CI, 0.58 to 0.92).

The reasons for the divergent outcomes in the above trials is not very clear. The three trials discussed above had slightly different patient populations- there were more cases of patients with no prior endocrine exposure (with de novo stage IV metastatic disease) in the SWOG S0226 trial compared with the FACT trial. The FACT trial included a more heterogeneous population of both premenopausal and postmenopausal women with locally advanced and metastatic disease. The SoFEA trial only enrolled patients with acquired endocrine resistance (who had disease progression while they were receiving an aromatase inhibitor). Further studies are needed to confirm the results of the SWOG S0226 trial.

The NCCN Panel has included an AI and fulvestrant as first-line therapy (category 1) for postmenopausal patients based on the above data.

**Monotherapy with endocrine agents:** In postmenopausal women there is evidence supporting the use of an AI as first-line therapy for their recurrent disease.

Prospective randomized trials comparing the AI head-to-head have demonstrated that all AI’s are the same. Tamoxifen is the commonly used SERM for premenopausal women. In postmenopausal women, AI monotherapy has been shown to have superior outcome compared with tamoxifen, although the differences are modest. A randomized phase III trial comparing tamoxifen with exemestane as first-line endocrine therapy for postmenopausal women with metastatic breast cancer showed no significant differences PFS or OS between the two arms.

**NCCN recommendations for first-line therapy:** For postmenopausal women with HR-positive, HER2-negative recurrent/stage IV breast cancer, NCCN category 1, preferred regimens include a cyclin-dependent kinase (CDK) 4/6 inhibitor with an aromatase inhibitor (AI); fulvestrant with or without a CDK 4/6 inhibitor; Fulvestrant with a non-steroidal AI. The NCCN category 2A, preferred regimen includes non-steroidal AI (anastrozole, letrozole); steroidal aromatase inhibitor (exemestane), and selective estrogen receptor modulator (tamoxifen or toremifene). For premenopausal women, first-line endocrine treatment includes ovarian suppression/ablation and endocrine therapy listed above for postmenopausal women or alternately with a selective estrogen- receptor modulator (SERM) alone.

**Preferred regimens for Second and Subsequent Lines of therapy for HR- Positive, HER2-Negative Breast Cancer**

**Fulvestrant containing regimens**
Fulvestrant + CDK 4/6 inhibitors: Fulvestrant in combination with a CDK 4/6 inhibitor may be offered to patients who experienced progression during prior treatment with AIs with or without one line of prior chemotherapy (category 1), because PFS was improved compared with fulvestrant alone in a phase III trial (PALOMA-3).502 The NCCN panel notes that treatment should be limited to those without prior exposure to CDK 4/6 inhibitors. The phase III trial (PALOMA-3) compared the combination of palbociclib and fulvestrant to fulvestrant in pre- or post-menopausal HR-positive, HER2-negative advanced breast cancer patients, whose disease progressed on prior endocrine therapy. Pre- or peri-menopausal patients also received goserelin. The median PFS was 9.5 months for the combination compared to 4.6 months for fulvestrant (HR 0.46, \( P < .000001 \)).503 Grade 3/4 adverse events of palbociclib and fulvestrant were mainly confined to neutropenia (in 65% of patients).

In the MONARCH 2 phase III trial, patients who had progressed while receiving endocrine therapy were randomly assigned to fulvestrant with or without abemaciclib.504 Those receiving combination therapy experienced an improved PFS relative to those receiving fulvestrant alone (16.4 versus 9.3 months; HR 0.55, 95% CI 0.45-0.68). The ORR was higher in those receiving abemaciclib and fulvestrant (48% vs. 21%).504 In addition, an improvement was seen in OS with abemaciclib plus fulvestrant compared with fulvestrant alone (46.7 versus 37.3 months; HR 0.757 95% CI 0.606-0.945).505

Based on the above data that shows addition of a CDK 4/6 inhibitor to fulvestrant in patients previously exposed to prior endocrine therapy, provides a significant improvement in median PFS, the NCCN Panel has included fulvestrant in combination with a CDK 4/6 inhibitor as a category 1 first-line option for postmenopausal women and premenopausal women with ovarian ablation/suppression with HR-positive, HER2-negative recurrent/stage IV breast cancer. The panel notes that if there is disease progression while on CDK4/6 inhibitor therapy, there are limited data to support an additional line of therapy with another CDK4/6-containing regimen.

Fulvestrant monotherapy: Fulvestrant monotherapy appears to be at least as effective as anastrozole in patients whose disease progressed on previous tamoxifen.506,507 A randomized phase II study compared anastrozole versus fulvestrant in over 200 patients with advanced breast cancer.481,482 In the initial analysis, fulvestrant was as effective as anastrozole in terms of ORR (36.0% vs. 35.5%; odds ratio, 1.02; 95% CI, 0.56 –1.87; \( P = .947 \)) in evaluable patients (n = 89 for fulvestrant and n = 93 for anastrozole).481 An improved time to progression was seen with fulvestrant compared to anastrozole (median time to progression was 23.4 months for fulvestrant vs. 13.1 months for anastrozole; HR, 0.63; 95% CI, 0.39–1.00; \( P = .0496 \)).482 This study used a higher 500 mg loading dose every 2 weeks for 3 doses and then 500 mg monthly.481 The median OS was observed to be longer in the fulvestrant group than in the anastrozole group (54.1 months vs. 48.4 months; HR, 0.70; \( P = .041 \)).483

A phase II study of fulvestrant in postmenopausal women with advanced breast cancer and disease progression following aromatase inhibitor therapy documented a partial response rate of 14.3% with an additional 20.8% of patients achieving stable disease for at least 6 months.508 The clinical benefit rates of exemestane versus fulvestrant observed in a phase III trial of postmenopausal women with HR-positive advanced breast cancer who experienced disease progression on prior nonsteroidal aromatase inhibitor therapy were comparable (32.2% vs. 31.5%; \( P = .853 \)).509 In that study, fulvestrant was administered as a 500 mg loading dose followed by doses of 250 mg on day 14, day 28, and then monthly.509

Fulvestrant plus alpelisib: In a randomized phase III trial of patients (n=572) with advanced HR-positive breast cancer and confirmed
phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic subunit alpha (PIK3CA) status, all of whom had received a prior AI either for local or advanced disease. Patients were enrolled into either PIK3CA mutant (n=341) cohort or the PIK3CA non-mutant cohort and each cohort was randomized to receive fulvestrant plus the phosphoinositide 3-kinase (PI3K) inhibitor, alpelisib versus fulvestrant plus placebo. Patients with PIK3CA mutation, receiving alpelisib showed improved PFS compared to fulvestrant alone. At a median follow-up of 20 months PFS was 11.0 months (95% confidence interval [CI], 7.5 to 14.5) in the alpelisib group compared with 5.7 months (95% CI, 3.7 to 7.4) in the group that received fulvestrant alone (HR for progression or death, 0.65; 95% CI, 0.50 to 0.85; P < .001); in the cohort without PIK3CA-mutated tumors, the HR was 0.85 (95% CI, 0.58 to 1.25). In the overall population, the most frequently reported grade 3 or 4 adverse events seen with alpelisib and fulvestrant versus fulvestrant alone were hyperglycemia (36.6% vs.0.7%); rash (9.9% vs. 0.3%) and diarrhea (grade 3) ( 6.7% vs. 0.3%); no diarrhea or rash of grade 4 was reported.510

Everolimus plus endocrine therapy: Resistance to endocrine therapy in women with HR-positive disease is frequent. One mechanism of resistance to endocrine therapy is activation of the mammalian target of rapamycin (mTOR) signal transduction pathway.

A randomized phase II study estimated the efficacy of tamoxifen alone versus tamoxifen combined with everolimus, an oral inhibitor of mTOR, in women with HR-positive, HER2-negative metastatic breast cancer previously treated with an aromatase inhibitor.511 After a median follow-up of 13 months, an intent-to-treat analysis showed that the clinical benefit was 42.1% (95% CI, 29.1–55.9) with tamoxifen alone and 61.1% (95% CI, 46.9–74.1) with tamoxifen plus everolimus. An improvement in median time to progression was seen when everolimus was combined with tamoxifen compared with tamoxifen alone. Median time to progression was 4.5 months (95% CI, 3.7–8.7) with tamoxifen alone versus 8.5 months (95% CI, 6.01–13.9) with everolimus and tamoxifen.511

A phase III trial in postmenopausal women with advanced, HR-positive breast cancer with no prior endocrine therapy for advanced disease, randomized subjects to letrozole with or without the mTOR inhibitor temsirolimus has been reported.512 In this study, PFS was not different between the treatment arms (HR, 0.89; 95% CI, 0.75–1.05; long-rank P = .18).

The results of this trial differ from that of the BOLERO-2 trial (described below). The reasons for the differences in the outcomes of these two randomized phase III studies is uncertain, but may be related to the issues of patient selection and extent of prior endocrine therapy.

A phase III study (BOLERO-2) randomized postmenopausal women with HR-positive advanced breast cancer that had progressed or recurred during treatment with a nonsteroidal aromatase inhibitor to exemestane with or without the mTOR inhibitor everolimus.514 Final results reported after median 18-month follow-up show that median PFS (by central review) remained significantly longer with everolimus plus exemestane versus placebo plus exemestane at 11.0 versus 4.1 months, respectively; (HR, 0.38; 95% CI, 0.31–0.48; P < .0001). The adverse events (all grades) that occurred more frequently in those receiving everolimus included stomatitis, infections, rash, pneumonitis, and hyperglycemia.513,514 Analysis of safety and efficacy in the elderly patients enrolled in this trial showed that elderly patients treated with an everolimus-containing regimen had similar incidences of these adverse events, but the younger patients had more on-treatment deaths.515 Based on the evidence from the BOLERO-2 trial, the NCCN Panel has included everolimus plus exemestane as an option for women who fulfill the entry criteria for BOLERO-2. Tamoxifen or fulvestrant in combination with everolimus have also been included as options. The NCCN panel also notes that if there is
disease progression while on an everolimus-containing regimen, there are no data to support an additional line of therapy with another everolimus regimen.

Aromatase inhibitors: Aromatase Inhibitors as monotherapy are options as subsequent-line therapy. The three AIs (anastrozole, letrozole, and exemestane) have shown similar efficacy in the second-line setting.\(^{495,516,517}\) AI monotherapy may be useful in patients desiring single-agent treatment, if they have not received an AI as first-line treatment or in patients who may not be suitable for combination therapy. Patients who have received a prior nonsteroidal AI may benefit from a steroidal AI as subsequent-line therapy or vice versa.

Selective estrogen receptors modulator: An analysis of two randomized studies of first-line treatment with anastrozole followed by second-line tamoxifen and vice versa showed that tamoxifen is effective as second-line option.\(^{518}\)

**NCCN recommendations for second-line:** For postmenopausal women with HR-positive, HER2-positive recurrent/stage IV breast cancer, the preferred options available include fulvestrant with a CDK 4/6 inhibitor (palbociclib, ribociclib, abemaciclib) (category 1), or for those with tumor PIK3CA mutations, fulvestrant with alpelisib, everolimus with either an AI, tamoxifen or fulvestrant; monotherapy with fulvestrant, non-steroidal or steroidal AI, or SERM. Estrogen receptor 1 (ESR1) activating mutations are frequently detected in patients with prior exposure to AIs. Tumors with these mutations are generally resistant to both AIs and tamoxifen. Certain tumors with these mutations retain sensitivity to fulvestrant. All may benefit from the addition of a CDK 4/6-inhibitor, mTOR-inhibitor, or alpelisib in combination with fulvestrant if tumor has PIK3CA mutation.

**Regimens Useful in Certain Circumstances for Therapy for HR-Positive, HER2-Negative Breast Cancer**

Megestrol acetate,\(^{493,519-521}\) estradiol\(^{522}\) androgens such as fluoxymesterone, and single agent abemaciclib have been listed as options useful in certain circumstances.

The phase II MONARCH 1 trial, evaluated the activity of abemaciclib as a single agent in patients (n =132) with refractory HR-positive, HER2-negative metastatic breast cancer who had progressed on endocrine therapy and already received multiple systemic therapies (average of three prior systemic regimens).\(^{523}\) Ninety percent of patients had visceral disease and 50.8% had more than three sites of metastases.\(^{523}\) Single-agent abemaciclib induced partial response in 26 (19.7%) and demonstrated an ORR of 19.7% (95% CI: 13.3–27.5).\(^{523}\) Median PFS was 6 months (95% CI: 4.2–7.5). At the final analysis, at 18 months, median OS was 22.3 months (95% CI: 17.7–not reached).\(^{523}\) Diarrhea was the most frequent adverse event reported in 90.2% patients. Other common adverse events were fatigue (65.2%), nausea (64.4%) and decreased appetite (45.5%). Grade 3 and 4 neutropenia occurred in 26.9% of patients.\(^{523}\) The NCCN panel has included single agent abemaciclib as an option for those with disease progression on prior endocrine therapy and prior chemotherapy in the metastatic setting.

**Systemic Therapy for Stage IV or Recurrent HR-Negative, HER2-Positive Breast Cancer**

For patients with HER2-positive, HR-negative recurrent/stage IV breast cancer, the treatment approach is HER2-targeted therapy in combination with systemic chemotherapy. The NCCN panel notes that an FDA-approved biosimilar is an appropriate substitute for trastuzumab. Also, trastuzumab and hyaluronidase-oysk injection for subcutaneous use may be substituted for trastuzumab. This subcutaneous option has different dosage and administration instructions compared to intravenous trastuzumab. Doses and schedules of representative regimens for use in HER2-positive metastatic breast cancer are also included in NCCN Guidelines.
Patients progressing on a HER2-targeted therapy should be offered additional subsequent treatment with a HER2-targeted therapy since it is beneficial to continue suppression of the HER2 pathway. The choice of the HER2-targeted therapy will depend on previously administered therapy, relapse-free interval, and patients’ preference and access.

The optimal sequence of available HER2-targeted therapies and the optimal duration of HER2-targeted therapy for recurrent/stage IV is currently unknown. The NCCN panel recommends continuing HER2-targeted therapy until progression/unacceptable toxicity.

**Preferred Regimens for Stage IV/Recurrent HER2-Positive Breast Cancer**

A randomized, double-blind, phase III study (CLEOPATRA) compared the efficacy and safety of pertuzumab in combination with trastuzumab and docetaxel versus trastuzumab and docetaxel as first-line treatment for 808 women (n=808) with HER2-positive metastatic breast cancer.524 This trial included patients (about 10%) who had previously received trastuzumab in the adjuvant or neoadjuvant setting. At a median follow-up of 19 months, the addition of pertuzumab to docetaxel plus trastuzumab resulted in improvement in PFS compared with placebo (median, 18.5 versus 12.4 months; hazard ratio [HR] 0.62, 95% CI 0.51-0.75, P < .001).524 At a median follow-up of 30 months the results showed a statistically significant improvement in OS in favor of the pertuzumab-containing regimen, with a 34% reduction in the risk of death (HR, 0.66; 95% CI, 0.52–0.84; P = .0008).388 The most common adverse reactions reported in the pertuzumab group compared to the control group were diarrhea (67% vs. 46%), rash (34% vs. 24%), mucosal inflammation (27% vs. 20%), febrile neutropenia (14% vs. 8%), and dry skin (10% vs. 4%). Peripheral edema and constipation were greater in the control group.524 Cardiac adverse events or left ventricular systolic dysfunction were reported slightly more frequently in the control group.525 Health-related QOL was not different in the two treatment groups.526 In the PERUSE study, patients (n=1436) with advanced HER2-positive breast cancer and no prior systemic therapy (except endocrine therapy) received docetaxel, paclitaxel or nab-paclitaxel with trastuzumab and pertuzumab until disease progression or unacceptable toxicity. The preliminary results after 52 months median follow-up, show that median PFS was comparable between docetaxel, paclitaxel and nab-paclitaxel (median PFS reported was 19.6, 23.0 and 18.1 months with docetaxel, paclitaxel and nab-paclitaxel, respectively).527 Compared with docetaxel-containing therapy, paclitaxel-containing therapy was associated with more neuropathy (31% vs. 16%), but less febrile neutropenia (1% vs. 11%) and mucositis (14% vs. 25%). Phase II trials have also found activity and tolerability for pertuzumab, pertuzumab with trastuzumab, and for other regimens combining pertuzumab and trastuzumab together with other active cytotoxic agents (i.e., paclitaxel, vinorelbine).528,529,530 Phase III trials of pertuzumab plus chemotherapy without trastuzumab have not been reported.

The NCCN Panel recommends pertuzumab plus trastuzumab in combination with a taxane as a preferred option for first-line treatment of patients with HER2-positive metastatic breast cancer. Pertuzumab plus trastuzumab in combination with docetaxel is an NCCN category 1 and in combination with paclitaxel is an NCCN category 2A recommendation.

**Other Regimens for Regimens for Stage IV/Recurrent HER2-Positive Breast Cancer**

Ado-trastuzumab emtansine (T-DM1): T-DM1 is an antibody-drug conjugate that stably links the HER2-targeting property of trastuzumab to the cytotoxic activity of the microtubule-inhibitory agent DM1 (derivative of maytansine).

In a phase III trial (MARIANNE), 1,095 patients with locally advanced or metastatic breast cancer were randomized to first-line treatment with T-DM1 with or without pertuzumab or trastuzumab plus a taxane. The
primary endpoints were safety and PFS assessed by independent review. The PFS for T-DM1 with pertuzumab was found non-inferior to trastuzumab and a taxane (15.2 and 13.7 months respectively; HR, 0.87; 97.5% CI, 0.69–1.08; \( P = .14 \)).\(^{531}\) The PFS for T-DM1 alone was non-inferior to trastuzumab plus a taxane (14.1 and 13.7, respectively; HR, 0.91; 97.5% CI, 0.73–1.13; \( P = .31 \)).\(^{531}\) The incidence of Grade 3–5 adverse events was 54.1%, 45.4%, and 46.2% in the trastuzumab plus a taxane arm, T-DM1 arm, and T-DM1 plus pertuzumab arm, respectively. Health-related QOL was maintained for a longer duration with a median of 7.7 months for T-DM1 (HR, 0.70; 95% CI, 0.57–0.86) and a median of 9 months for T-DM1 plus pertuzumab (HR, 0.68; 95% CI, 0.55–0.84) compared with a median of 3.9 months for trastuzumab and a taxane.\(^{531}\)

Based on the MARIANNE trial data demonstrating T-DM1 and T-DM1 with pertuzumab being non-inferior, with better QOL compared with trastuzumab plus taxane and possibly better-tolerated for some patients,\(^ {531}\) the NCCN Panel included T-DM1 as an option for treatment of patients with HER2-positive metastatic breast cancer. Pertuzumab, trastuzumab, and a taxane, however, remains the preferred first-line regimen for HER2-positive metastatic disease based on data demonstrating improved OS compared to trastuzumab and a taxane. TDM-1 as first-line therapy should be considered only in those not suitable for the preferred treatment.

First-line trastuzumab in combination with selected chemotherapy\(^ {532}\) are additional options for HER2-positive metastatic breast cancer patients. Randomized trials demonstrate benefit from adding trastuzumab to other agents including paclitaxel with or without carboplatin,\(^ {532,536}\) docetaxel,\(^ {533}\) and vinorelbine,\(^ {533}\) for patients with HER2-positive metastatic disease. In addition, the combination of trastuzumab and capecitabine has also shown efficacy as a first-line trastuzumab-containing regimen in this setting.\(^ {536,537}\) The NCCN panel believes the 27% frequency of significant cardiac dysfunction in patients treated with the combination of trastuzumab and doxorubicin/cyclophosphamide chemotherapy in the metastatic setting is too high for use of this combination outside the confines of a prospective clinical trial.\(^ {532,537,538}\)

In those with disease progression on first-line trastuzumab-containing regimens, the NCCN Panel recommends continuation of HER2 blockade. This recommendation also applies to patients who are diagnosed with HER2-positive metastatic disease after prior exposure to trastuzumab in the adjuvant setting. Several trials have demonstrated benefit of continuation of trastuzumab therapy following disease progression on a trastuzumab-containing regimen.\(^ {539-541}\) However, the optimal duration of trastuzumab in patients with long-term control of disease is unknown.

Pertuzumab is active in patients beyond the first-line setting. The results of a multicenter, open-label, single-arm, phase II study (\( n = 66 \)) show that the combination of pertuzumab and trastuzumab is active and well tolerated in patients with HER2-positive metastatic breast cancer that has progressed on prior trastuzumab therapy.\(^ {542}\) The trial reported an objective response rate of 24.2% (16 patients out of 66). The median PFS time observed with pertuzumab and trastuzumab combination was 15.5 months (range, 0.9–17.0 months; 80% CI, 18-31 months).\(^ {542}\) The reported median duration of response with the combination was 5.8 months (range, 2.9–15.3 months).\(^ {542}\)

To determine whether the clinical benefit seen in the study was from pertuzumab alone or was a result of the combined effect of pertuzumab and trastuzumab, a cohort of patients (\( n = 29 \)) whose disease progressed during prior trastuzumab-based therapy received pertuzumab monotherapy until progressive disease or unacceptable toxicity. Of these, patients with disease progression (\( n = 17 \)) continued to receive pertuzumab with the addition of trastuzumab. In the 29 patients who received pertuzumab monotherapy, the objective response rate and clinical benefit rate reported were 3.4% and 10.3%, respectively, whereas
in the patients who received dual blockade after progression on pertuzumab, the objective response rate and clinical benefit rate were 17.6% and 41.2%, respectively.543

According to the NCCN Panel, for patients with disease progression after treatment with trastuzumab-based therapy without pertuzumab, a line of therapy containing both trastuzumab plus pertuzumab with or without a cytotoxic agent (such as vinorelbine or taxane) may be considered. Further research is needed to determine the ideal sequencing strategy for HER2-targeted therapy.

T-DM1 also has also shown activity in the second-line setting. A randomized, international, multicenter, open-label, phase III study (EMILIA) evaluated the safety and efficacy of T-DM1 compared with lapatinib plus capecitabine for HER2-positive patients with locally advanced breast cancer or metastatic breast cancer previously treated with trastuzumab and a taxane.544 The primary endpoints of this study were PFS, OS, and safety. T-DM1 demonstrated a statistically significant improvement in both primary endpoints of PFS and OS. PFS (assessed by independent review) was significantly improved with T-DM1 with median PFS of 9.6 months vs. 6.4 months with lapatinib plus capecitabine; HR for progression or death from any cause was 0.65 (95% CI, 0.55–0.77; P < .001). At the first interim analysis, T-DM1 also demonstrated significant improvement in OS. The stratified HR for death from any cause with T-DM1 versus lapatinib plus capecitabine was 0.62 (95% CI, 0.48–0.81; P = .0005).544 Rates of grade 3 or 4 adverse events were higher with lapatinib plus capecitabine than with T-DM1 (57% vs. 41%). The incidences of thrombocytopenia and increased serum aminotransferase levels were higher with T-DM1 (frequency >25%), whereas the incidences of diarrhea, nausea, vomiting, and palmar-plantar erythrodysesthesia were higher with lapatinib plus capecitabine.544

A phase II single-arm study evaluated fam-trastuzumab deruxtecan-nxki, a HER2 antibody conjugated with a topoisomerase I inhibitor, in adults (n=184) with pathologically documented HER2-positive metastatic breast cancer who had received multiple previous treatments including treatment with T-DM1.545 After a median duration of follow-up of 11.1 months (range 0.7- to 19.9), the median response duration with fam-trastuzumab deruxtecan-nxki was 14.8 months (95% CI, 13.8 to 16.9), and the median PFS was 16.4 months (95% CI, 12.7 to not reached).545 Most commonly reported adverse events (grade 3 or higher) were a decreased neutrophil count (20.7%), anemia (in 8.7%), nausea (in 7.6%), and fatigue (6%).545 Interstitial lung disease (ILD) was reported in 13.6% of the patients (grade 1 or 2 - 10.9%; grade 3 or 4 - 0.5%; and grade 5 - 2.2%). Based on this study and the approval from the U.S. FDA, the NCCN panel has included this as an option for HER-2 positive metastatic disease noting that it is indicated in patients after two or more lines of prior HER2-targeted therapy regimens in the metastatic setting and contraindicated for those with a history of or active ILD.

Lapatinib in combination with capecitabine or trastuzumab are options for patients with HER2-positive disease following progression on a trastuzumab-containing regimen.

A phase III study compared lapatinib plus capecitabine with capecitabine alone in women with advanced or metastatic breast cancer refractory to trastuzumab in the metastatic setting and with prior treatment with an anthracycline and a taxane in either the metastatic or adjuvant setting.546 Time to progression was increased in the group receiving combination therapy when compared with the group receiving capecitabine monotherapy (8.4 months vs. 4.4 months; HR, 0.49; 95% CI, 0.34–0.71; P < .001). The patients who progressed on monotherapy were allowed to cross over to the combination arm. This resulted in insufficient power to detect significant differences in OS; an exploratory analysis demonstrated
a trend toward a survival advantage with lapatinib plus capecitabine. The analysis reported a median OS of 75.0 weeks for the combination arm and 64.7 weeks for the monotherapy arm (HR, 0.87; 95% CI, 0.71–1.08; P = .210).

Results from a phase III trial in which patients with heavily pretreated metastatic breast cancer and disease progression on trastuzumab therapy randomly assigned to trastuzumab plus lapatinib or lapatinib monotherapy showed that PFS was increased from 8.1 weeks to 12 weeks (P = .008) with the combination. The OS analysis data showed that lapatinib plus trastuzumab improved median survival by 4.5 months, with median OS of 14 months for the combination therapy and 9.5 months for lapatinib alone (HR, 0.74; 95% CI, 0.57–0.97; P = .026). This improvement in OS analysis included patients who were initially assigned to monotherapy and crossed over to receive combination therapy at the time of progression. Based on the absence of data, the panel does not recommend the addition of chemotherapy to the trastuzumab and lapatinib combination.

In a phase II trial of patients (n=49) with progressive, HER2-positive disease and brain metastases (92% received CNS surgery and/or radiotherapy), were treated with capecitabine plus neratinib, a second-generation (irreversible) pan-HER TKI inhibitor of the tyrosine kinase domains of EGFR, HER2 and HER4. The patients were separated based on prior lapatinib treatment. The combination therapy resulted in a CNS objective response rate of 49% (95% CI, 32% to 66%), among lapatinib-naïve patients, and 33% (95% CI, 10% to 65%) among those with prior lapatinib treatment. Median PFS and OS among lapatinib-naïve patients was 5.5 and 13.3 months, and 3.1 and 15.1 months among those with prior lapatinib treatment. Grade 3 diarrhea occurred in 29% of patients.

A prospective randomized phase III trial (NALA) randomized patients (n = 621) with HER2-positive to neratinib in combination with capecitabine or lapatinib plus capecitabine until disease progression. All enrolled patients received a least two lines of prior HER2-targeted treatment in the metastatic setting. Approximately 30% had received ≥3 prior treatment lines. About a third of all patients had received prior treatment with trastuzumab, pertuzumab and T-DM1.

The ORR (32.8 % vs. 26.7%; P = .1201), the clinical benefit rate (44.5% vs 35.6%; P = .0328), and median duration of response (8.5 vs 5.6 months) all favored the neratinib arm. Fewer patients required intervention for CNS metastases with neratinib. The risk of progression was reduced by 24% in the neratinib group (HR 0.76; 95% CI 0.63–0.93; P = .0059). There was a non-significant trend towards improved survival. The OS rates at 6 and 12 months were 90.2% vs 87.5% with neratinib + capecitabine compared with 72.5% vs 66.7% for lapatinib in combination with capecitabine (HR = 0.88; 95% CI 0.72–1.07; P= .2086). Diarrhea was the most frequent side effect in the NALA trial in both arms, but a higher rate was observed in patients in the neratinib group (any grade diarrhea 83% vs. 66%; grade 3/4 diarrhea 24% vs. 13%).

Based on the results of the NALA trial and the recent FDA approval, NCCN has included neratinib plus capecitabine as a category 2A option in this setting.

Systemic Therapy for Recurrent or Stage IV HR- Positive, HER2-Positive Breast Cancer

Women with Stage IV or recurrent disease characterized by tumors that are HR-positive, HER2-positive tumors have the option of receiving HER2-directed therapy as a component of their treatment plan. Options include, treatment with a HER2-targeted therapy plus chemotherapy or endocrine therapy alone or in combination with HER2-targeted therapy. Endocrine therapy alone or in combination with HER2-targeted therapy is a less toxic approach compared with HER2-targeted therapy combined
with chemotherapy. Premenopausal women treated with HER2-targeted therapy and endocrine therapy should receive ovarian suppression or ablation.

Adding trastuzumab or lapatinib to an AI has demonstrated a PFS advantage compared with AI alone in post-menopausal women with stage IV or recurrent HR-positive, HER2-positive tumors.

In the TAnDEM study, postmenopausal women (n=207) with metastatic HR-positive and HER2-positive tumors were randomized to receive anastrozole alone or anastrozole plus trastuzumab. Compared with single-agent anastrozole, an improvement in PFS was seen with combination therapy (4.8 vs. 2.4 months; HR 0.63, 95% CI 0.47-0.84, \( P = .0016 \)). The combination was associated with a higher incidence of toxicities (all grades) fatigue (21% vs. 9%), diarrhea (20% vs. 8%), vomiting (21% vs. 4%), and pyrexia (18% vs. 7%); serious (grade 3/4) toxicities were rare in both treatment arms.

The phase III eLEcTRA trial studied the efficacy and safety of trastuzumab plus letrozole in patients (n=93) with HER2-positive and HR-positive metastatic breast cancer. Median time to progression was 3.3 months with letrozole and 14.1 months with trastuzumab plus letrozole. The results are consistent with the TAnDEM trial, however, due to smaller numbers of patients enrolled in this trial, this was not statistically significant (HR, 0.67; 95% CI, 0.35 to 1.29; \( P = .23 \)).

In a phase III study of postmenopausal patients (n=219) with HER2–positive and HR–positive disease, first-line treatment with lapatinib plus letrozole reduced the risk of disease progression compared to treatment with letrozole alone (median PFS, 8.2 months vs 3.0 months; HR, 0.71, 95% CI, 0.53 to 0.96; \( P = .019 \)). The combination of letrozole plus trastuzumab was associated with a higher rate of grade 3 or grade 4 toxicities, including diarrhea (10% vs. 1%) and rash (1% vs. 0%).

In the randomized phase II study (PERTAIN), postmenopausal women (n=258) were randomly assigned to either first-line pertuzumab plus trastuzumab and an AI (anastrozole or letrozole) or trastuzumab plus an AI. There was an improvement in PFS with the three-drug combination (18.9 versus 15.8 months; HR 0.65, 95% CI 0.48-0.89). Grade 3 or higher adverse events observed were higher trastuzumab and pertuzumab versus pertuzumab alone (50% vs. 39%). Of note, about half of women received induction therapy with a taxane for 18 to 24 weeks prior to the initiation of endocrine therapy. Based on the results of the PERTAIN trial, the NCCN panel notes that if treatment was initiated with chemotherapy and trastuzumab plus pertuzumab, and the chemotherapy was stopped, endocrine therapy may be added to the trastuzumab plus pertuzumab.

In the ALTERNATIVE trial, postmenopausal women (n=355) with HER2-positive, HR-positive metastatic breast cancer were randomized to receive lapatinib plus trastuzumab plus an AI, lapatinib plus an AI, or trastuzumab plus AI without chemotherapy. All patients in the trial received prior trastuzumab and prior endocrine therapy, either in the adjuvant or metastatic disease setting. AI in combination with lapatinib plus trastuzumab demonstrated significant increase in PFS compared with trastuzumab without lapatinib (11 vs. 5.7 months; HR 0.62, 95% CI 0.45-0.88, \( P = .0064 \)). Most common adverse events with the combination compared with trastuzumab or lapatinib monotherapy were diarrhea (69%, 9%, 51%), rash (36%, 2%, 28%), nausea (22%, 9%, 22%), and paronychia (30%, 0, 15%).

The NCCN Panel has also included other combinations of available endocrine therapies such as fulvestrant or tamoxifen with trastuzumab as options for HR-positive and HER2-positive metastatic disease. These options would be mostly considered after completion of chemotherapy plus HER2-therapy or in a few patients with indolent or asymptomatic
Systemic Therapy for Recurrent or Stage IV Disease with germline BRCA1/2 mutations

About 5% of all patients with breast cancer carry the germline breast cancer susceptibility gene (BRCA) mutations and rates of these mutations are higher rates among those with HER2-negative disease.\(^{557,558}\)

**PARP inhibitors:** The phase III OlympiAD trial randomized patients (n=302) with metastatic breast cancer harboring the germline BRCA mutations to the PARP inhibitor, olaparib (n=205) or physicians choice (n=97) of non-platinum chemotherapy (capecitabine, eribulin or vinorelbine).\(^{559}\) An improvement in PFS was seen in those receiving olaparib relative to those receiving chemotherapy [7.0 vs. 4.2 months; HR: 0.58; 95% CI: 0.43–0.80; \(P<.001\)].\(^{559}\) The study, included all subtypes- those with HR-positive, HER2-negative and positive disease, and triple negative. The PFS improvements noted with olaparib were noted in all subtypes and greatest in the triple-negative population. Subsequent follow-up did not show a statistically significant difference in OS between treatment arms and the study was also not powered to evaluate OS. The median OS with olaparib compared with treatment of physician’s choice was 19.3 months versus 17.1 months, respectively (HR 0.90, 95% CI 0.66-1.23; \(P=.513\)).\(^{560}\) The QOL was significantly better in the olaparib arm. It is interesting to note that patients who had not received prior chemotherapy in the metastatic setting achieved a 7.9-month longer median OS with olaparib compared with treatment of physician’s choice.\(^{560}\)

The phase III EMBRACA trial patients with advanced breast cancer harboring the germline BRCA mutations to a PARP inhibitor, were randomized to talazoparib (n=287) or to physicians choice of single agent chemotherapy (n=144).\(^{561}\) The median PFS among patients in the talazoparib group was longer than the control group (8.6 months [95% CI, 7.2 to 9.3] vs. 5.6 months [95% CI, 4.2 to 6.7]; HR for disease progression or death, 0.54; 95% CI, 0.41 to 0.71; \(P<.001\)).\(^{561}\)

Based on the results of the above phase II trials, the two FDA approved PARP inhibitors- olaparib and talazoparib are included as a category 1, preferred options for those with germline BRCA1/2 mutations. The NCCN Panel recommends assessing for germline BRCA1/2 mutations in all patients with recurrent or metastatic breast cancer to identify candidates for PARP inhibitor therapy. While olaparib and talazoparib are FDA indicated in HER2-negative disease, the NCCN Panel supports use in any breast cancer subtype associated with germline BRCA1/2 mutations.

**Platinums:** The phase III, TNT trial compared docetaxel with carboplatin in the first-line setting in women (n=376) with triple negative breast cancer. In the unselected population, carboplatin was not more active than docetaxel (ORR, 31.4% vs. 34.0%; \(P=.66\)).\(^{562}\) Patients with a germline BRCA1/2 mutation had a significantly better response to carboplatin than docetaxel (ORR, 68.0% vs. 33.3%, absolute difference 34.7%, \(P=.03\)).\(^{562}\) PFS was also improved with carboplatin treatment in patients with a germline BRCA1/2 mutation (median PFS 6.8 months vs. 4.4 months), no difference was found in OS. However, patients with somatic BRCA 1/2 mutation in the tumor DNA did not appear to have the same advantage.

For those with triple negative recurrent/stage IV breast cancer and germline BRCA1/2 mutations, the NCCN Panel has included platinum agents (cisplatin and carboplatin) as preferred treatment options. It is unknown how PARP-inhibitors compare with platinums in this setting.
**Systemic Therapy for PD-L1–Positive, Triple Negative, Recurrent or Stage IV Disease**

In a randomized trial (IMpassion 130), patients (n= 902) with triple negative breast cancer who had not received treatment in the metastatic setting were randomized to the programmed cell death ligand 1 (PD-L1) inhibitor, atezolizumab plus albumin-bound paclitaxel or placebo plus albumin-bound paclitaxel.563 All patients enrolled in the trial had to have completed previous chemotherapy (preoperative or adjuvant) at least 12 months before randomization and not received any chemotherapy in the metastatic setting. At a median follow-up of 12.9 months, there was statistically significant difference in PFS in those receiving atezolizumab plus albumin-bound paclitaxel than in the placebo plus albumin-bound paclitaxel (7.2 vs. 5.5 months; HR for progression or death 0.80, 95% CI 0.69-0.92), and a nonsignificant trend towards improved OS (21.3 vs. 17.6 months; HR for death 0.84, 95% CI 0.69-1.02).563 However, in a planned subset analysis of patients with PD-L1-expressing tumors, treatment with atezolizumab plus albumin-bound paclitaxel showed statistically significant improvement in PFS (7.5 vs. 5 months; HR 0.62, 95% CI 0.49-0.78), and OS (25 vs. 15.5 months; HR 0.62, 95% CI 0.45-0.86).563 Grade 3 or higher adverse events occurred in 48.7% receiving atezolizumab plus albumin-bound paclitaxel versus 42.2% receiving placebo plus albumin-bound paclitaxel. Grade 3 or 4 neuropathy was more frequently seen among those receiving atezolizumab (5.5% vs. 2.7%). There were 3 treatment-related deaths among the patients who received atezolizumab, consistent with other studies of checkpoint inhibitors. Adverse events led to treatment discontinuation in 16% in the atezolizumab arm versus 8% in the control arm.563 PD-L1-positive expression in tumor-infiltrating immune cells of 1% or more has been associated with a better outcome with PD-L1 inhibitor treatment.564 A subsequent 18-month follow-up analysis confirmed PFS and OS benefits among those with PD-L1-expressing tumors.565 Atezolizumab plus albumin-bound paclitaxel is included as a preferred option for those with advanced triple negative breast cancer with PD-L1 expression in ≥1% tumor-infiltrating immune cells.

**Systemic Chemotherapy for Recurrent or Stage IV Disease**

Women with HR-negative tumors not localized to the bone or soft tissue only, or that are associated with symptomatic visceral metastasis irrespective of HR- or HER-status, or that have HR-positive tumors that are refractory to endocrine therapy should receive systemic chemotherapy.

A variety of chemotherapy regimens are felt to be appropriate, as outlined in the treatment algorithm. Combination chemotherapy generally provides higher rates of objective response and longer time to progression, in comparison to single-agent chemotherapy. Combination chemotherapy is, however, associated with an increase in toxicity and is of little survival benefit.566–570 Furthermore, administering single agents sequentially decreases the likelihood that dose reductions will be needed. Thus, the NCCN Panel finds no compelling evidence that combination chemotherapy is superior to sequential single agents. Therefore, sequential monotherapy is the preferred and combination therapy is useful in patients with rapid clinical progression or need for rapid symptom and/or disease control.

Usually the first-line regimens are given until progression or unacceptable toxicity. Considering what is unacceptable toxicity and considering no further cytotoxic therapy should be decided together with the patient. Adverse effects may require dose reduction and cessation of chemotherapy prior to disease progression.

The NCCN panel recommends considering scalp cooling to reduce incidence of chemotherapy-induced alopecia for patients receiving chemotherapy. The data on efficacy of scalp cooling is mainly from the...
The NCCN Panel has classified the chemotherapy agents into three categories—preferred, other recommended and useful in certain circumstances. The treatment decision should be individualized and considering previous therapies, pre-existing comorbidities, nature of the disease, toxicity profiles, patient preferences and in some cases access to agents.

Among preferred single agents, the NCCN Panel has included taxanes (paclitaxel), anthracyclines (doxorubicin and liposomal doxorubicin), anti-metabolites (capecitabine and gemcitabine), microtubule inhibitors (eribulin and vinorelbine), platinum agents for patients with triple negative tumors and germline BRCA 1/2 mutations.

Paclitaxel can be administered weekly (80 mg/m²) or every three weeks (175 mg/m²). A meta-analysis of randomized controlled trials that compared weekly and every three weeks taxanes regimens in advanced breast cancer showed that compared with every three-week treatment, weekly administration of paclitaxel resulted in an improvement in OS (HR 0.78, 95% CI 0.67-0.89).

Doxorubicin (60 to 75 mg/m²) every three weeks, or 20 mg/m2 weekly has shown an ORR between 30 to 47%. Liposomal doxorubicin (50 mg/m² every 4 weeks) has been shown to have efficacy similar to doxorubicin (60 mg/m² every 3 weeks). It has also been shown to have efficacy in the second-line setting for patients with metastatic breast cancer. Compared with doxorubicin, the liposomal doxorubicin has a less frequent dosing schedule and decreased risk of cardiotoxicity 7% vs. 26%, HR 3.16; 95% CI 1.58-6.31), decreased rate of nausea (37 % vs. 53%) and vomiting (19% vs. 31%), lower rates of alopecia (20% vs. 66%), and neutropenia (4% vs. 10%). However, compared with doxorubicin it was associated with a higher rate of plantar-plantar erythrodysesthesia (48% vs. 2%), stomatitis (22% vs. 15%), and mucositis (23% vs 13%).
The benefit of capecitabine as a treatment option for patients with metastatic breast cancer has been demonstrated in multiple phase II trials. Results of one study of patients (n=126) treated with capecitabine showed ORR of 28%, median TTP of 4.9 months and median OS of 15.2 months (95% CI: 13.5–19.6 months). In another study, women (n=95) were randomized to capecitabine or cyclophosphamide, methotrexate and fluorouracil (CMF). Treatment with single agent capecitabine resulted in a higher ORR compared with CMF (30% vs. 16%). The median TTP and OS were similar in both groups.

Eribulin is a non-taxane microtubule inhibitor used for the treatment of patients with metastatic breast cancer who have previously received at least two chemotherapeutic regimens for the treatment of metastatic disease. Prior therapy should have included an anthracycline and a taxane in either the adjuvant or metastatic setting. In a phase III trial, patients (n=762) with metastatic breast cancer were randomized 2:1 to eribulin or treatment of physicians’ choice. The OS was improved in women assigned to eribulin (median 13.1 months, 95% CI 11.8–14.3) compared with those receiving other treatments (10.6 months, 9.3–12.5), a 19% statistically significant risk reduction (HR 0.81, 95% CI 0.66–0.99; P= .041).

A phase III trial compared eribulin with capecitabine in patients with metastatic breast cancer and showed that both treatments were similar with respect to OS and PFS. The median PFS times for eribulin and capecitabine were 4.1 and 4.2 months, respectively (HR, 1.08; 95% CI, 0.93 to 1.25; P=.30) and the OS with eribulin versus capecitabine was 15.9 months versus 14.5 months; HR 0.88, 95% CI 0.77–1.00).

In addition to the above, gemcitabine and vinorelbine are both active as a single agents even in heavily pretreated patients with metastatic breast cancer.

Among other recommended single agents, the NCCN Panel has included taxanes (docetaxel, album-bound paclitaxel), anthracyclines (epirubicin), and ixabepilone as other recommended regimens.

Ixabepilone as monotherapy has been evaluated in several phase II trials of women with metastatic breast cancer: in a first-line setting in patients previously treated with anthracycline chemotherapy, in patients with taxane-resistant metastatic breast cancer, and in patients with advanced breast cancer resistant to an anthracycline, a taxane, and capecitabine. In the phase II trials, objective response rate, median duration of response, and median OS duration were 41.5% (95% CI, 29.4–54.4%), 8.2 months (95% CI, 5.7–10.2 months), and 22.0 months (95% CI, 15.6–27.0 months) in the first-line setting; 12% (95% CI, 4.7–26.5%), 10.4 months, and 7.9 months for the taxane-resistant patients; 11.5% (95% CI, 6.3–18.9%), 5.7 months, and 8.6 months for the patients previously treated with an anthracycline, a taxane, and capecitabine. In the study by Perez et al grade 3/4 treatment-related toxicities included peripheral sensory neuropathy (14%) and neutropenia (54%).

The NCCN Panel had included combination chemotherapy regimens as useful in certain circumstances. The combination regimen options include doxorubicin/cyclophosphamide (AC), epirubicin/cyclophosphamide (EC), docetaxel and capecitabine, gemcitabine and paclitaxel (GT), cyclophosphamide/methotrexate/fluorouracil (CMF), gemcitabine/carboplatin, carboplatin with paclitaxel or albumin-bound paclitaxel, and paclitaxel/bevacizumab.

For the doublet regimens that are included, randomized phase III trials have shown that the ORR with first-line AC treatment ranges from 47% to 54%) and OS is around 20 months. For first-line EC the ORR reported from phase III trial is 7.1 months and OS of 14 months. For first-line capecitabine/docetaxel, a phase III trial reported an ORR of 53%
and time-to-progression of 11 months. In the second-line setting, another phase III trial compared the efficacy and tolerability of capecitabine/docetaxel therapy in anthracycline-pretreated patients and showed significantly superior efficacy in time to disease progression (HR, 0.652; 95% CI, 0.545 to 0.780; P = .0001; median, 6.1 vs. 4.2 months), OS (HR, 0.775; 95% CI, 0.634 to 0.947; P = .0126; median, 14.5 vs. 11.5 months), and ORR (42% v 30%, P = .006) compared with single agent docetaxel.

Combination chemotherapy regimens containing a platinum agent or a taxane have been shown to be efficacious in patients with metastatic triple negative breast cancer. A randomized phase II study compared the addition of iniparib to gemcitabine/carboplatin versus gemcitabine/carboplatin in patients with triple negative breast cancer who had received no more than two prior chemotherapies. ORR was similar in both groups - 30.2% (95% CI, 24.6 to 35.8) with gemcitabine/carboplatin and the median OS was 11.1 months with gemcitabine/carboplatin [HR of 0.88 (95% CI, 0.69 to 1.12)].

Several phase II studies have evaluated the efficacy of paclitaxel/carboplatin as first-line for patients with metastatic breast cancer and found the combination to be an effective therapeutic option in this setting. The randomized trial, tnAcity, evaluated the efficacy and safety of first-line albumin-bound paclitaxel plus carboplatin, albumin-bound paclitaxel plus gemcitabine, and gemcitabine plus carboplatin in patients with metastatic triple negative breast cancer. The results of this trial reported that median PFS was significantly longer with albumin-bound paclitaxel plus carboplatin versus albumin-bound paclitaxel/gemcitabine (8.3 vs. 5.5 months; HR, 0.59 [95% CI, 0.38–0.92]; P = .02) or gemcitabine/carboplatin (8.3 vs. 6.0 months; HR, 0.58 [95% CI, 0.37–0.90]; P = .02). The median OS was also longer with albumin-bound paclitaxel plus carboplatin versus albumin-bound paclitaxel/gemcitabine (16.8 vs. 12.1 months; HR, 0.73 [95% CI, 0.47–1.13]; P = .16) or gemcitabine/carboplatin (16.8 vs. 12.6 months; HR, 0.80 [95% CI, 0.52–1.22]; P = .29). The ORR was 73%, 39%, and 44%, respectively.

A series of trials have sought to define the role for bevacizumab in the treatment of metastatic breast cancer. The E2100 trial randomized 722 women with recurrent or metastatic breast cancer to first-line chemotherapy with paclitaxel with or without bevacizumab. This trial documented superior PFS (11.8 months vs. 5.9 months; HR 0.60; P < .001) favoring bevacizumab plus paclitaxel compared with paclitaxel alone. A similar trial enrolled 736 patients who were randomized to treatment with docetaxel and bevacizumab or docetaxel and placebo. This trial also documented increased PFS in the arm containing bevacizumab (10.1 months vs. 8.2 months with docetaxel alone; HR 0.77; P = .006). An additional trial, RIBBON-1, combined bevacizumab with paclitaxel, with a taxane (docetaxel, nab-paclitaxel), with anthracyclines (FEC, CAF, AC, or EC), or with the same chemotherapy alone. Results of this trial show a statistically significant increase in PFS with bevacizumab and paclitaxel (8.6 months vs. 5.7 months; HR, 0.69; P < .001) and taxane- or anthracycline- (9.2 months vs. 8.0 months; HR, 0.64; P < .001) containing arms. In a subset analysis of the phase III CALGB 40502 trial, patients (n = 201) with metastatic triple negative breast cancer, first-line albumin-bound paclitaxel in combination with bevacizumab resulted in a median PFS of 7.4 months.

The NCCN panel notes that albumin-bound paclitaxel may be substituted for paclitaxel or docetaxel due to medical necessity (i.e., hypersensitivity reaction). If substituted for weekly paclitaxel or docetaxel, then the weekly dose of nab-paclitaxel should not exceed 125 mg/m².

The data from the above-mentioned randomized trials, document that the addition of bevacizumab to first- or second-line chemotherapy agents
modestly improves time to progression and response rates. The
time-to-progression impact may vary among cytotoxic agents and appears
greatest with bevacizumab in combination with weekly paclitaxel. None of
these studies demonstrates an increase in OS or QOL when analyzed
alone or in a meta-analyses of the trials. Therefore, the NCCN Panel
has included bevacizumab in combination with paclitaxel as an option
useful in only select circumstances.

The only triplet regimen listed as an option in the metastatic setting is
CMF. This regimen was compared in the first-line setting with capecitabine
monotherapy, and results show similar ORR and PFS. However, CMF
resulted in a shorter OS (median, 22 versus 18 months; HR 0.72, 95% CI
0.55-0.94) compared to capecitabine.

Additional Targeted Therapies for Stage IV disease Useful in Certain
Circumstances
Neurotrophic tropomyosin receptor kinase (NTRK) gene fusions are seen
in of a few rare types of cancer, such as secretory carcinoma of
the breast or salivary gland and infantile fibrosarcoma and also
infrequently in some common cancers, such as melanoma, glioma and
carcinomas of the thyroid, lung and colon. NTRK fusions are identified
by fluorescence in situ hybridization (FISH), Next Generation Sequencing
(NGS) or polymerase chain reaction (PCR). Larotrectinib and
entrectinib are two NTRK-inhibitors that are U.S FDA approved for
the treatment of solid tumors that have an NTRK gene fusion without a
known acquired resistance mutation and have no satisfactory alternative
treatments or that have progressed following treatment. If patient with
recurrent/stage IV breast presents with a tumor with an NTRK fusion,
treatment with a NTRK-inhibitor is an option if no satisfactory alternative
treatments exists or that have progressed following treatment.

Pembrolizumab is U.S FDA approved for the treatment of patients with
unresectable or metastatic, microsatellite instability-high (MSI-H) or
mismatch repair deficient (dMMR) solid tumors that have progressed
following prior treatment and who have no satisfactory alternative
treatment options. Pembrolizumab has demonstrated anti-tumor
activity in heavily pre-treated patients with metastatic breast cancer and
tumor mutation burden (greater than or equal to 9
mutations/megabase) determined by commercially available tests. If
patient with recurrent/stage IV breast cancer presents has a tumor with
MSI-H/MMR mutation, whose disease has progressed following prior
treatments and no satisfactory alternative treatment options, treatment
pembrolizumab is an option.

Monitoring Metastatic Disease
Monitoring the treatment of metastatic breast cancer involves a wide array
of assessments and the need for the clinician to integrate several different
forms of information to decide on the effectiveness of treatment and the
acceptability of toxicity. The information includes those from direct
observations of the patient, including patient-reported symptoms,
performance status, change in weight, and physical examination;
laboratory tests such as alkaline phosphatase, liver function, blood counts,
and calcium; radiographic imaging; functional imaging; and, where
appropriate, tumor biomarkers. The results of these evaluations generally
are classified as response, continued response to treatment, stable
disease, uncertainty regarding disease status, or progression of disease.
The clinician typically must assess and balance multiple different forms of
information to decide along with the patient, whether disease is being
controlled and the toxicity of treatment is acceptable. Sometimes individual
pieces of information can be conflicting with regards to disease response,
and clinical judgement along with patient input is critical.

The NCCN Panel recommends using widely accepted criteria for reporting
response, stability, and progression of disease such as the RECIST
criteria and the WHO criteria. The Panel also recommends using the

same method of response assessment over time. For example, an abnormality initially found on diagnostic CT scan of the chest should be monitored with repeat diagnostic CT scans of the chest.

The optimal frequency of testing is uncertain, and is primarily based on the monitoring strategies utilized in breast cancer clinical trials. The page titled *Principles of Monitoring Metastatic Disease* in the algorithm provides a table outlining general recommendations for the frequency and type of monitoring as a baseline before initiation of new therapy, for monitoring the effectiveness of cytotoxic chemotherapy and endocrine therapy, and as an assessment when there is evidence of disease progression. The panel has indicated in a footnote that the frequency of monitoring can be reduced in patients who have long-term stable disease. These are guidelines and should be modified for the individual patient using clinical judgment, especially for those with stable or responding disease for long periods of time.

The clinical use of Circulating Tumor Cells (CTC) or circulating DNA (ctDNA) in metastatic breast cancer is not yet included in the NCCN Guidelines for Breast Cancer for disease assessment and monitoring. Patients with persistently increased CTC after 3 weeks of first-line chemotherapy have a poor PFS and OS. In spite of its prognostic ability, CTC count has failed to show a predictive value. A prospective, randomized, phase 3 trial (SWOG S0500) evaluated the clinical utility of serial enumeration of CTC in patients with metastatic breast cancer. According to the study results, switching to an alternative cytotoxic therapy after 3 weeks of first-line chemotherapy in patients with persistently increased CTC did not affect either PFS or OS.
Special Situations

Paget’s Disease

Paget’s disease of the breast is a rare manifestation of breast cancer characterized by neoplastic cells in the epidermis of the NAC. It most commonly presents with eczema of the areola, bleeding, ulceration, and itching of the nipple. The diagnosis is often delayed because of the rare nature of the condition and confusion with other dermatologic conditions. There is an associated cancer elsewhere in the breast in up to about 80% to 90% of cases. The associated cancers are not necessarily located adjacent to the NAC and may be either DCIS or invasive cancer.

Women with clinical signs that raise suspicion for Paget’s disease require a complete history and physical examination and diagnostic breast imaging. Any breast lesion identified by imaging or examination should be evaluated according to the NCCN Guidelines for Breast Screening and Diagnosis. The skin of the NAC should undergo surgical biopsy, including the full thickness of the epidermis including at least a portion of any clinically involved NAC. When biopsy of the NAC is positive for Paget’s disease, breast MRI is recommended to define the extent of disease and identify additional disease.

There are no category 1 data that specifically address local management of Paget’s disease. Systemic therapy is based on the stage and biological characteristics of any underlying cancer, and is supported by the evidence cited in the relevant stage-specific breast cancer treatment guidelines.

Management of Paget’s disease has traditionally been total mastectomy with axillary dissection. Total mastectomy remains a reasonable option for patients regardless of the absence or presence of an associated breast cancer. Data demonstrate that satisfactory local control may be achieved with breast-conserving surgery including the excision with negative margins of any underlying breast cancer along with resection of the NAC followed by whole breast radiation therapy. The risk of ipsilateral breast recurrence after breast-conserving NAC resection and radiation therapy with or without an associated cancer is similar to that with breast-conserving surgery and radiation therapy with the typical invasive or in situ cancer.

For Paget’s disease without an associated cancer (ie, no palpable mass or imaging abnormality), it is recommended that breast-conserving surgery consist of removal of the entire NAC with a negative margin of underlying breast tissue. In cases with an associated cancer elsewhere in the breast, the surgery includes removal of the NAC with a negative margin and removal of the peripheral cancer using standard breast-conserving technique to achieve a negative margin. It is not necessary to remove the NAC and the peripheral cancer in continuity in a single surgical specimen or through a single incision. Mastectomy also remains an appropriate treatment option.

ALN staging is not necessary when breast-conserving therapy is used to treat Paget’s disease with underlying DCIS without evidence of invasive cancer following clinical examination, imaging evaluation, and full-thickness skin biopsy of the involved NAC. In the presence of an underlying invasive breast cancer treated with breast-conserving surgery, axillary surgery should be performed according to the Surgical Axillary Staging outlined in the NCCN Guidelines. In cases treated by total mastectomy, axillary staging is recommended for patients with invasive disease and should also be considered for patients with underlying DCIS without evidence of invasive disease. This is because the final pathology may reveal an invasive cancer in the mastectomy specimen and the mastectomy precludes subsequent sentinel node biopsy. Two retrospective studies have provided evidence for a high degree of accuracy in the identification of the sentinel node(s) in patients with Paget’s disease. Patients treated with breast conservation should...
receive whole breast radiation. Extended-field radiation to regional lymph nodes should be used in cases of an associated invasive breast cancer with involved lymph nodes as for any breast cancer as described in the initial sections of the NCCN Guidelines. A radiation boost should be considered for the site of the resected NAC and any associated resected cancer site, if applicable.

Women with an associated invasive cancer have substantial risk of developing metastases. Adjuvant systemic therapy should be administered according to the stage of the cancer. Women with Paget’s disease treated with breast conservation and without an associated cancer or those with associated ER-positive DCIS should consider tamoxifen for risk reduction. Those with an associated invasive cancer should receive adjuvant systemic therapy based on the stage and HR status.
Phyllodes Tumors of the Breast
(also known as phyllodes tumors, cystosarcoma phyllodes)

Phyllodes tumors of the breast are rare tumors comprised of both stromal and epithelial elements.\(^{644}\) Phyllodes tumors exist in benign, borderline, and malignant subtypes, although there is not uniform agreement on the criteria for assigning subtype or for predicting biological behavior.\(^{645}\) The subtype of phyllodes tumor appears less important for risk of recurrence than does the margin of tumor-free resection achieved by surgical treatment. Diagnosis of phyllodes tumors prior to excisional biopsy/lumpectomy is uncommon. Phyllodes tumors occur in an older age distribution than fibroadenoma, a younger age distribution than the invasive ductal and lobular cancers, and with a mean age of 40.\(^{646}\) Phyllodes tumors often enlarge rapidly and are usually painless. Phyllodes tumors often appear on ultrasound and mammography as fibroadenomas, and FNA cytology and even core needle biopsy are inadequate to reliably distinguish phyllodes tumors from fibroadenoma.\(^{646}\) Thus, in the setting of a large or rapidly enlarging clinical fibroadenoma, excisional biopsy should be considered to pathologically exclude a phyllodes tumor. Patients with Li-Fraumeni syndrome (germline TP53 mutation, see NCCN Guidelines for Genetic/Familial High Risk Assessment) have an increased risk for phyllodes tumors.\(^{647}\) Local recurrences of phyllodes tumors are the most common site of recurrence. Most distant recurrences occur in the lung, and may be solid nodules or thin-walled cavities.

Treatment of phyllodes tumors (which includes benign, borderline, and malignant subtypes) is with local surgical excision with tumor-free margins of 1 cm or greater. Lumpectomy or partial mastectomy is the preferred surgical therapy. Total mastectomy is necessary only if negative margins cannot be obtained by lumpectomy or partial mastectomy.\(^{648}\) Since phyllodes tumors rarely metastasize to the ALNs, surgical axillary staging or ALN dissection is not necessary unless the lymph nodes are pathologic on clinical examination.\(^{649}\) In those patients who experience a local recurrence, resection of the recurrence with wide, tumor-free surgical margins should be performed. Some panel members recommend local radiation therapy of the remaining breast or chest wall following resection of a local recurrence, but this recommendation is controversial (category 2B).\(^{650}\)

While the epithelial component of most phyllodes tumors contains ER (58%) and/or PR (75%),\(^{651}\) endocrine therapy has no proven role in the treatment of phyllodes tumors. Similarly, there is no evidence that adjuvant cytotoxic chemotherapy provides benefit in reduction of recurrences or death. In the rare patient who experiences a systemic recurrence (usually in the lung), treatment should be as recommended in the NCCN Guidelines for Soft Tissue Sarcoma.
Breast Cancer During Pregnancy

Breast cancer occurring concurrently with pregnancy is an infrequent clinical event. In a California registry study, there were 1.3 breast cancers diagnosed per 10,000 live births. Unfortunately, breast cancer during pregnancy is most often ALN-positive and with larger primary tumor size. Histologically the tumors are poorly differentiated, are more frequently ER/PR-negative, and approximately 30% are HER2-positive. The diagnosis is often delayed because neither the patient nor the physician suspects malignancy.

Evaluation of the pregnant patient with suspected breast cancer should include a physical examination with particular attention to the breast and regional lymph nodes. Mammogram of the breast with shielding can be done safely and the accuracy is reported to be greater than 80%. Ultrasound of the breast and regional lymph nodes can be used to assess the extent of disease and also to guide biopsy. Ultrasound has been reported to be abnormal in up to 100% of breast cancers occurring during pregnancy. Biopsies for cytologic evaluation of a suspicious breast mass may be done with FNA of the breast and suspicious lymph nodes. However, the preferred technique is core needle biopsy. This provides tissue for histologic confirmation of invasive disease as well as adequate tissue for HR and HER2 analyses.

Staging assessment of the pregnant patient with breast cancer may be guided by clinical disease stage. The staging studies should be tailored to minimize fetal exposure to radiation. For clinically node-negative T1-T2 tumors, a chest x-ray (with shielding), liver function and renal function assessment, and a CBC with differential are appropriate. In patients who have clinically node-positive or T3 breast lesions, in addition to the aforementioned, an ultrasound of the liver and consideration of a screening MRI of the thoracic and lumbar spine without contrast may be employed. The documentation of the presence of metastases may alter the treatment plan and influence the patient’s decision regarding maintenance of the pregnancy. Assessment of the pregnancy should include a maternal fetal medicine consultation and review of antecedent maternal risks such as hypertension, diabetes, and complications with prior pregnancies. Documentation of fetal growth and development and fetal age by means of ultrasonographic assessment is appropriate. Estimation of the date of the delivery will help with systemic chemotherapy planning. In addition, maternal fetal medicine consultation should include counseling regarding maintaining or terminating pregnancy. Counseling of the pregnant patient with breast cancer should include a review of the treatment options, which include mastectomy or breast-conserving surgery as well as the use of systemic therapy. The most common surgical procedure has been modified radical mastectomy. However, breast-conserving surgery is possible if radiation therapy can be delayed to the postpartum period, and breast-conserving therapy during pregnancy does not appear to have a negative impact on survival. When surgery is performed at 25 weeks of gestation or later, obstetrical and prenatal specialists must be onsite and immediately available in the event of precipitous delivery of a viable fetus.

Although there are a limited number of isolated case reports and small retrospective studies evaluating use of SLN biopsy in pregnant patients, the sensitivity and specificity of the procedure has not been established in this setting. Thus, there are insufficient data on which to base recommendations for its use in pregnant women. Decisions related to use of SLN biopsy in pregnancy should be individualized. A review of the relative and absolute contraindications to sentinel node biopsy concluded that sentinel node biopsy should not be offered to pregnant women under 30 weeks gestation. There are limited data with only case reports and estimations of fetal radiation dose regarding use of radioactive tracer (eg, technetium 99m sulfur colloid). Isosulfan blue or...
methylene blue dye for sentinel node biopsy procedures is discouraged during pregnancy.

The indications for systemic chemotherapy are the same in the pregnant patient as in the non-pregnant breast cancer patient, although chemotherapy should not be administered at any point during the first trimester of pregnancy. The largest experience in pregnancy has been with anthracycline and alkylating agent chemotherapy. Collected data of chemotherapy exposure in utero indicate that the first trimester has the greatest risk of fetal malformation. Fetal malformation risks in the second and third trimester are approximately 1.3%, not different than that of fetuses not exposed to chemotherapy during pregnancy. If systemic therapy is initiated, fetal monitoring prior to each chemotherapy cycle is appropriate. Chemotherapy during pregnancy should not be given after week 35 of pregnancy or within 3 weeks of planned delivery in order to avoid the potential for hematologic complications during delivery. Data from a single-institution prospective study indicate that FAC chemotherapy (5-FU 500 mg/m² IV days 1 and 4, doxorubicin 50 mg/m² by IV infusion over 72 hours, and cyclophosphamide 500 mg/m² IV day 1) may be given with relative safety during the second and third trimesters of pregnancy. As reported by Gwyn et al, the median gestational age at delivery was 38 weeks, more than 50% of the patients had a vaginal delivery, and there were no fetal deaths. An update of this experience reported on 57 women treated with FAC in the adjuvant or neoadjuvant setting. There were 57 live births. A survey of parents/guardians reported on the health of 40 children. There was one child with Down syndrome and two with congenital abnormalities (club foot, congenital bilateral ureteral reflux). The children are reported to be healthy and progressing well in school. Ondansetron, lorazepam, and dexamethasone can be used as part of the pre-chemotherapy antiemetic regimen.

There are limited data on the use of taxanes during pregnancy. If used, the NCCN Panel recommends weekly administration of paclitaxel after the first trimester if clinically indicated by disease status. There are only case reports of trastuzumab use during pregnancy. The majority of these case reports indicated oligo- or anhydramnios with administration of trastuzumab; fetal renal failure occurred in one case. If trastuzumab is otherwise indicated, it should be administered in the postpartum period; the panel recommends against its use during pregnancy.

A single case report of first trimester exposure to lapatinib during treatment for breast cancer reported an uncomplicated delivery of a healthy female neonate.

Endocrine therapy and radiation therapy are contraindicated during pregnancy. Endocrine therapy and radiation therapy, if indicated, should thus not be initiated until the postpartum period.

Communication between the oncologist and maternal fetal medicine specialist is essential at every visit and for every treatment decision point for the patient.
Inflammatory Breast Cancer

Inflammatory breast cancer (IBC) is a rare, aggressive form of breast cancer estimated to account for 1% to 6% of breast cancer cases in the United States.\textsuperscript{682,683} IBC is a clinical diagnosis that requires erythema and dermal edema (peau d’orange) of a third or more of the skin of the breast.

IBC is usually HR-negative and is more frequently HER2-positive than the usual ductal breast cancers. Studies on gene expression profiling of IBC have demonstrated that all the subtypes of IBC exist, but basal and HER2 overexpressed are more frequent.\textsuperscript{684-687} According to the 7th edition of the AJCC Cancer Staging Manual, IBC is classified as stage IIIB, stage IIIC, or stage IV breast cancer, depending on the degree of nodal involvement and whether distant metastases are present. The primary tumor of IBC is classified as T4d by definition, even when no mass is specifically apparent in the breast. On radiographic imaging, findings of skin thickening and, in some cases, an underlying mass are observed. Despite use of the term “inflammatory,” the characteristic clinical features of IBC are due to blockage of dermal lymphatics by tumor emboli. Although a biopsy is required to evaluate for the presence of cancer in breast tissue and the dermal lymphatics, a diagnosis of IBC is based on clinical findings, and dermal lymphatic involvement is neither required, nor sufficient by itself, to assign a diagnosis of IBC.\textsuperscript{688,689} The differential diagnosis includes cellulitis of the breast and mastitis.

In the past, IBC has often been placed under the general heading of locally advanced breast cancer. There is a growing body of evidence that IBC patients, when compared with noninflammatory forms of locally advanced breast cancer, are more likely to have a less favorable prognosis\textsuperscript{690-692} and to be younger at the time of disease presentation.\textsuperscript{693}

The NCCN Panel acknowledges that studies focusing on genetic characterization of IBC are needed to more clearly define IBC as a disease entity and to optimize treatment.\textsuperscript{694,695} Nevertheless, current evidence provides justification for a separate guideline for the workup and treatment of patients diagnosed with IBC.

**Stage T4d, N0 - N3, M0**

**Workup**

Women with a clinical/pathologic diagnosis of IBC without distant metastasis (stage T4d, N0-N3, M0) should undergo a thorough staging evaluation by a multidisciplinary team.

Recommendations for workup include a complete history and physical examination involving a CBC and platelet count.

A pathology review and pre-chemotherapy determinations of tumor HR- and HER2- status should be performed. HER2 has a predictive role in determining which patients with IBC will benefit from HER2-targeted therapy. The NCCN Panel endorses the CAP protocol for pathology reporting (www.cap.org) and endorses the ASCO CAP recommendations for quality control performance of HER2 testing and interpretation of IHC and ISH results.\textsuperscript{696}

Imaging studies help facilitate image-guided biopsy, delineate locoregional disease, and identify distant metastases. Evaluation of all women suspected with IBC must include diagnostic bilateral mammogram, with the addition of ultrasound as necessary. A breast MRI scan is optional.

Evaluations for the presence of distant metastasis in the asymptomatic patient include LFTs, bone scan or sodium fluoride PET/CT (category 2B), and diagnostic CT imaging of the chest, abdomen, and pelvis (category 2B; category 2A for diagnostic CT imaging of the chest when pulmonary symptoms are present).
FDG PET/CT may be most helpful in situations where standard imaging results are equivocal or suspicious. However, there is limited evidence suggesting that PET/CT may be a useful adjunct to standard imaging of IBC due to the increased risk of regional lymph node involvement and distant spread of disease in this group of patients. Nevertheless, equivocal or suspicious sites identified by FDG PET/CT scanning or other imaging methods should be biopsied for confirmation of stage IV disease whenever possible. FDG PET/CT is a category 2B recommendation. The consensus of the panel is that FDG PET/CT can be performed at the same time as diagnostic CT. If FDG PET and diagnostic CT are performed and both clearly indicate bone metastases, bone scan or sodium fluoride PET/CT may not be needed.

Genetic counseling is recommended if the patient is considered to be at high risk for hereditary breast cancer as defined by the NCCN Guidelines for Genetic/Familial High-Risk Assessment: Breast and Ovarian.

Treatment
The treatment of patients with IBC should involve a combined modality approach comprising preoperative systemic therapy followed by surgery (mastectomy) and radiotherapy.

Preoperative Chemotherapy
There are no large randomized trials evaluating the optimal systemic treatment of IBC, since it is a rare disease. The systemic therapy recommendations are based on data from retrospective analyses, small prospective studies, and data from non-IBC, locally advanced breast cancer.

The benefit of preoperative systemic therapy followed by mastectomy over preoperative systemic therapy alone in patients with IBC was shown in a retrospective analysis in which lower local recurrence rates and longer disease-specific survival were reported for the combined modality approach. Results from a large retrospective study of patients with IBC performed over a 20-year period at The University of Texas M.D. Anderson Cancer Center demonstrated that initial treatment with doxorubicin-based chemotherapy followed by local therapy (ie, radiation therapy or mastectomy, or both) and additional postoperative chemotherapy resulted in a 15-year DFS rate of 28%.

A retrospective study demonstrated that the addition of a taxane to an anthracycline-based regimen improved PFS and OS in patients with ER-negative IBC. A systematic review found evidence for an association between the intensity of preoperative therapy and the likelihood of a pCR. A study of IBC patients, with cytologically confirmed ALN metastases, treated with anthracycline-based chemotherapy with or without a taxane indicated that more patients receiving the anthracycline-taxane combination achieved a pCR compared with those who received only anthracycline-based therapy. In addition, patients who had a pCR in the ALNs had superior OS and DFS compared with those with residual axillary disease.

The NCCN Panel recommends preoperative systemic therapy with an anthracycline-based regimen with or without taxanes for the initial treatment of patients with IBC. The panel also recommends completing the planned chemotherapy prior to mastectomy. If the chemotherapy was not completed preoperatively, it should be completed postoperatively.

Targeted Therapy
All women with HR-positive IBC are recommended to receive endocrine therapy sequentially after completing the planned preoperative systemic therapy.

HER2-positive IBC is associated with a poor prognosis. For women with HER2-positive disease, the addition of trastuzumab to primary systemic chemotherapy is associated with better response rates.
prospective study that randomized women with locally advanced breast cancers, including those with IBC, to neoadjuvant anthracycline-based chemotherapy with or without trastuzumab for 1 year demonstrated that the addition of trastuzumab significantly improved the response rate and event-free survival. The NCCN Panel recommends inclusion of trastuzumab in the chemotherapy regimen and is recommended for patients with HER2-positive disease. There are no available data to indicate the optimal duration of trastuzumab, specifically among women with IBC. However, based on the available data, the panel recommends continuing trastuzumab therapy for up to 1 year.

Results of small phase II trials indicate that other HER2-targeting agents such as lapatinib and pertuzumab have a clinical benefit in IBC. The results of the NEOSPHERE trial that included patients with IBC showed increased pCR with the pertuzumab-containing regimens. Therefore, the NCCN Panel has included in a footnote that a pertuzumab-containing regimen may be administered preoperatively in patients with HER2-positive IBC.

Determination of response to neoadjuvant chemotherapy in IBC should include a combination of physical examination and radiologic assessment.

Surgery
Patients with a clinical/pathologic diagnosis of IBC should always be treated with chemotherapy before surgery. It has been known for many years that surgical treatment as primary treatment of patients with IBC is associated with poor outcomes. SLN dissection is not a reliable method of assessing ALNs among women with IBC. Use of breast-conserving surgery in patients with IBC has been associated with poor cosmesis, and limited data suggest that rates of local recurrence may be higher when compared with mastectomy. Breast-conserving therapy is not recommended for patients with IBC.

Mastectomy with level I/II ALN dissection is the recommended surgical procedure recommended by the NCCN Panel for patients who respond to neoadjuvant chemotherapy. The NCCN Panel has listed delayed breast reconstruction as an option that can be recommended to women with IBC who have undergone a modified radical mastectomy. Reconstruction of the breasts soon after mastectomy may compromise the post-mastectomy radiation therapy outcomes.

For patients with IBC who do not respond to preoperative systemic therapy, mastectomy is not generally recommended. Additional systemic chemotherapy and/or preoperative radiation should be considered for these patients. Patients with tumors responding to this secondary therapy should undergo mastectomy and subsequent treatment as described above.

Radiation
After mastectomy, radiation therapy is recommended after the completion of the planned chemotherapy.

The probability of locoregional lymph node involvement is high for women with IBC. To reduce the risk of local recurrence, the panel recommends radiation therapy to the chest wall and the supraclavicular region. If the internal mammary lymph node(s) is clinically or pathologically involved, radiation therapy should include the internal mammary nodes. If the internal mammary nodes are not clinically or pathologically involved, then including the internal mammary nodes in the radiation therapy field is at the discretion of the treating radiation oncologist (category 3). For HER2-positive disease, trastuzumab may be administered concomitantly with radiation therapy.
Stage IV or Recurrent IBC

Patients with stage IV or recurrent IBC should be treated according to the guidelines for recurrence/stage IV breast cancer (See NCCN Guidelines for Breast Cancer).
Axillary Breast Cancer

Occult breast cancer presenting with axillary metastases is an unusual presentation that can be a diagnostic and therapeutic challenge. Evidence to support recommendations on the management of patients presenting with axillary breast cancer comes from a limited number of retrospective studies involving small numbers of patients (see also references therein). Although treatment of women with axillary metastases from an unknown primary tumor has typically involved mastectomy and axillary nodal dissection, some of these patients have also been successfully treated with axillary nodal dissection followed by radiation therapy.

Patients with a suspected occult primary breast cancer will typically present to the oncologist after undergoing an initial biopsy: core needle biopsy (preferred), and/or FNA. Accurate pathologic assessment of the biopsied material is most important. Therefore, the pathologist must be consulted to determine whether the available biopsy material is adequate, or if additional biopsy material is necessary (eg, core needle, incisional, or excisional biopsy) to provide an accurate and complete diagnosis.

Workup for Possible Primary Breast Cancer

MRI of the breast can facilitate the identification of occult breast cancer, and can help select those patients most likely to benefit from mastectomy. For example, in a study of 40 patients with biopsy-proven breast cancer in the axilla, and a negative or indeterminate mammogram, MRI identified the primary breast lesion in 70% of the patients. In addition, of the 7 patients with a negative MRI who subsequently underwent ALN dissection and radiation therapy to the whole breast, no evidence of local recurrence was evident at a median follow-up of 19 months.

The NCCN Guidelines for Occult Primary Cancer provide guidance on the diagnosis and initial workup of patients with a suspicious axillary mass without any signs of a primary tumor. A small subset of these patients may have a primary cancer in the axillary tail of the breast. Adenocarcinoma with positive axillary nodes and mediastinal nodes in a woman is highly suggestive of a breast primary. Adenocarcinoma in the supraclavicular nodes, chest, peritoneum, retroperitoneum, liver, bone, or brain could also indicate primary breast cancer in women. The guidelines suggest the use of a mammogram and breast ultrasound for such patients.

Testing for immunohistochemical markers including ER/PR and HER2 is recommended. Elevated ER/PR levels provide strong evidence for a breast cancer diagnosis. MRI of the breast should be considered for a patient with histopathologic evidence of breast cancer when mammography and ultrasound are not adequate to assess the extent of the disease. MRI may be especially helpful in women with dense breast tissue, positive axillary nodes, and suspected occult primary breast tumor or to evaluate the chest wall. Breast MRI has been shown to be useful in identifying the primary site in patients with occult primary breast cancer and may also facilitate breast conservation in selected women by allowing for lumpectomy instead of mastectomy. In one report, the primary site was identified using MRI in about half of the women presenting with axillary metastases, irrespective of the breast density.

The NCCN Guidelines for Occult Primary Cancer also provide recommendations for additional workup, including chest and abdominal CT to evaluate for evidence of distant metastases for patients diagnosed with adenocarcinoma (or carcinoma not otherwise specified) of the axillary nodes without evidence of a primary breast lesion. In particular, breast MRI and ultrasound are recommended. Axillary ultrasound should also be performed.
Treatment for Possible Primary Breast Cancer
Patients with MRI-positive breast disease should undergo evaluation with ultrasound or MRI-guided biopsy and receive treatment according to the clinical stage of the breast cancer. Treatment recommendations for those with MRI-negative disease are based on nodal status. For patients with T0, N1, M0 disease, options include mastectomy plus axillary nodal dissection or axillary nodal dissection plus whole breast irradiation with or without nodal irradiation. Systemic chemotherapy, endocrine therapy, or trastuzumab is given according to the recommendations for stage II or III disease. Neoadjuvant chemotherapy, trastuzumab, and endocrine therapy should be considered for patients with T0, N2-N3, M0 disease followed by axillary nodal dissection and mastectomy as for patients with locally advanced disease.

Summary
The therapeutic options for patients with noninvasive or invasive breast cancer are complex and varied. In many situations, the patient and physician have the responsibility to jointly explore and select the most appropriate option from among the available alternatives. With few exceptions, the evaluation, treatment, and follow-up recommendations in these guidelines are based on the results of past and present clinical trials. However, there is not a single clinical situation in which the treatment of breast cancer has been optimized with respect to either maximizing cure or minimizing toxicity and disfigurement. Therefore, patient/physician participation in prospective clinical trials allows patients to not only receive state-of-the-art cancer treatment but also to contribute to improving the treatment outcomes.
