The NCCN Guidelines and the illustrations herein may not be reproduced in any form without the express written permission of NCCN. ©2019.

Updates in Version 2.2019 of the NCCN Guidelines for Penile Cancer from Version 1.2019 include:

### [MS-1](#)

- The discussion section has been updated to reflect the changes in the algorithm.

Updates in Version 1.2019 of the NCCN Guidelines for Penile Cancer from Version 2.2018 include:

### [Global Changes](#)

- The NCCN Categories of Preference have been applied to all systemic therapy treatment recommendations.

### [INTRO](#)

- This is a new page.

### [PN-2](#)

- T1, Grade 1-2 Primary Treatment: "Partial penectomy" added as an option.

### [PN-5](#)

- Top pathway, percutaneous lymph node biopsy positive treatment recommendations updated: "~~Consider~~ *Cisplatin-based* neoadjuvant chemotherapy followed by ILND or ILND (*in patients not eligible for cisplatin-based chemotherapy*)"

### [PN-8](#)

- Top pathway: Invasion of corpora cavernosa absent or present removed and changed to "Noninvasive" or "Invasive"

### [Principles of Penile Organ-Sparing Approaches](#)

#### [PN-A \(1 of 2\)](#)

- Laser therapy 3rd bullet updated: "A plume (smoke) evacuator is ~~recommended~~ *required* during penile laser treatments..."
- Spot size in commonly used settings row of the table updated:
  - CO2: "Spot size: ~~3 mm~~ *1–5 mm*"
  - Nd:YAG: "Spot size: ~~5 mm~~ *1–5 mm*"

#### [Principles of Systemic Therapy \(PN-D\)](#)

- Name of page was changed from "Principles of Chemotherapy" to "Principles of Systemic Therapy"
- These pages were extensively revised to apply the NCCN Categories of Preference.

INTRODUCTION

**NCCN and the NCCN Penile Cancer Panel believes that the best management for any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

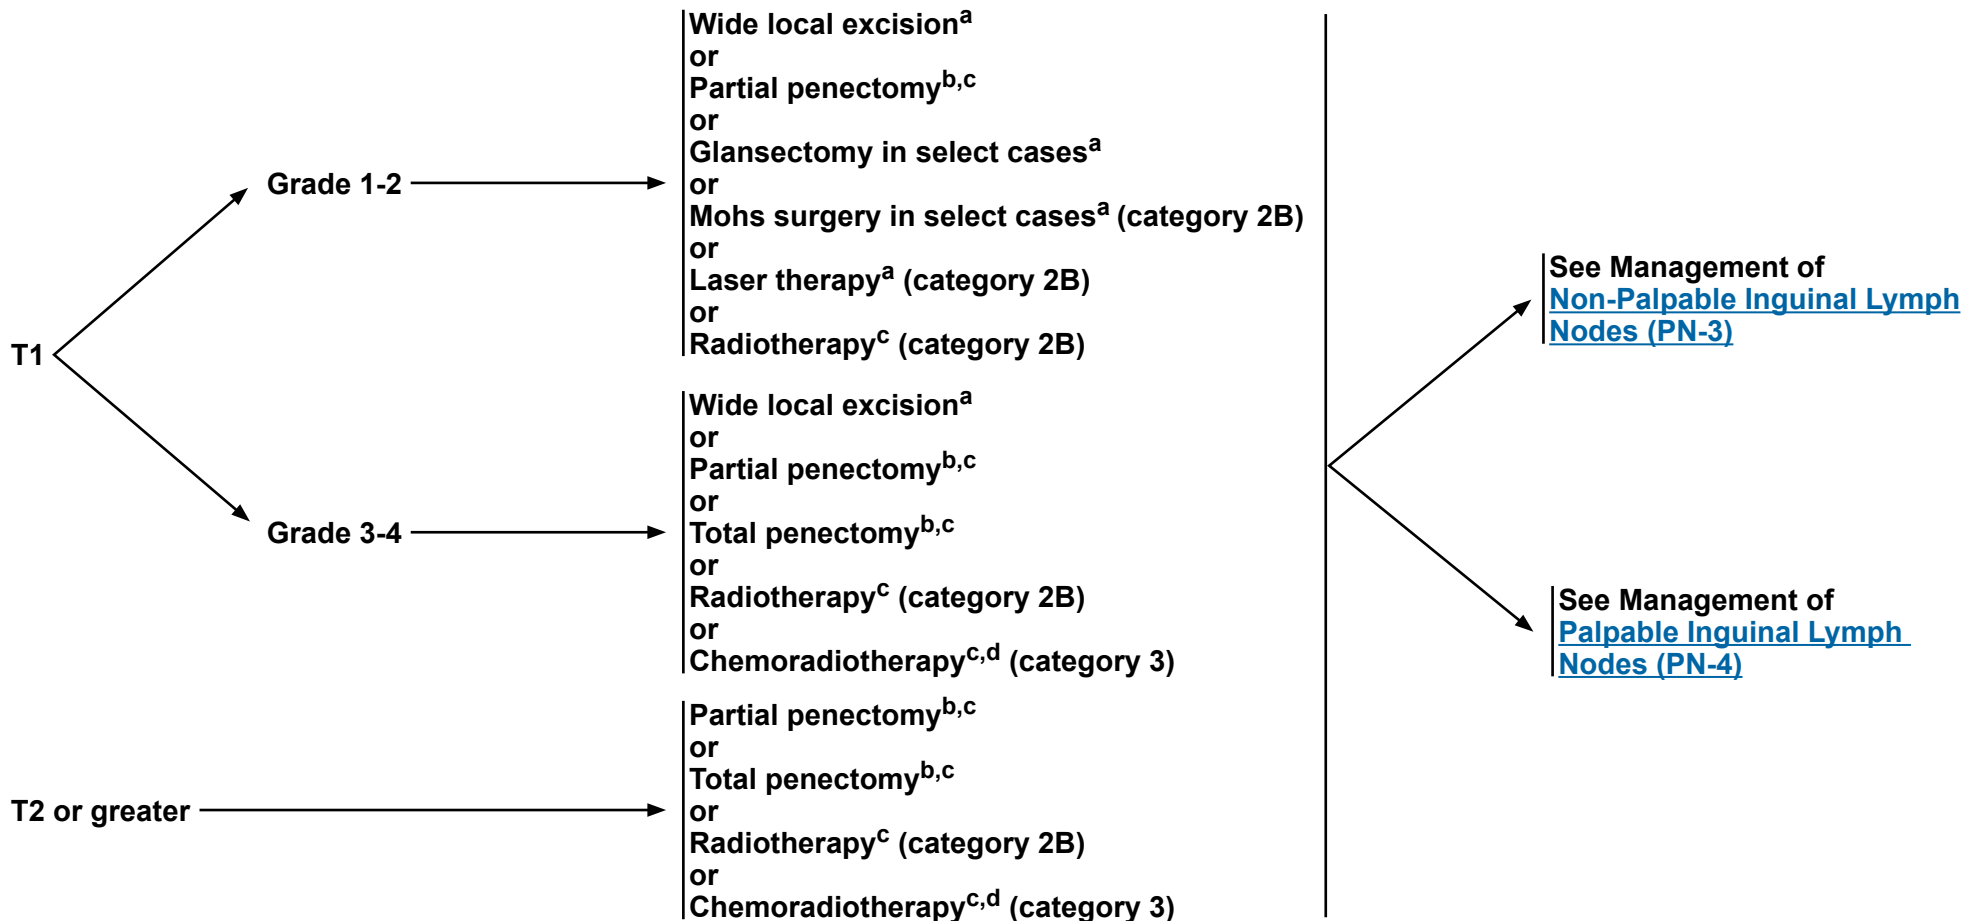

<sup>a</sup> See Principles of Penile Organ-Sparing Approaches (PN-A).

**Note:** All recommendations are category 2A unless otherwise indicated.  
**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### PATHOLOGIC DIAGNOSIS

### PRIMARY TREATMENT

<sup>a</sup> See Principles of Penile Organ-Sparing Approaches (PN-A).

<sup>b</sup> See Principles of Surgery (PN-B).

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### MANAGEMENT OF NON-PALPABLE INGUINAL LYMPH NODES

<sup>b</sup> [See Principles of Surgery \(PN-B\)](#).

<sup>e</sup> Ta verrucous carcinoma is by definition a well-differentiated tumor. Therefore, only surveillance of the inguinal lymph nodes is required.

<sup>f</sup> With contrast unless contraindicated.

<sup>g</sup> DSNB is recommended provided the treating physician has experience with this modality.

<sup>h</sup> If positive lymph nodes are found on DSNB, ILND is recommended.

<sup>i</sup> A modified/superficial inguinal dissection with intraoperative frozen section is an acceptable alternative to stage the inguinal lymph nodes.

<sup>j</sup> Consider prophylactic EBRT (category 2B) to inguinal lymph nodes in patients who are not surgical candidates or who decline surgical management.

**Note: All recommendations are category 2A unless otherwise indicated.**

**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

### MANAGEMENT OF PALPABLE NON-BULKY INGUINAL LYMPH NODES

<sup>b</sup> See Principles of Surgery (PN-B).

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

<sup>f</sup> With contrast unless contraindicated.

<sup>k</sup> CT/MRI of pelvis with contrast for nodal evaluation if difficult to assess on physical exam.

<sup>l</sup> Consider PET/CT scan (skull-base to mid-thigh).

<sup>m</sup> If M1 disease identified, see [Management of Metastatic Disease \(PN-9\)](#).

<sup>n</sup> The size threshold of 4 cm represents the largest diameter of contiguous inguinal lymph node(s) tissue as measured on either physical examination and/or axial imaging (CT or MRI) and suspected of harboring metastatic disease.

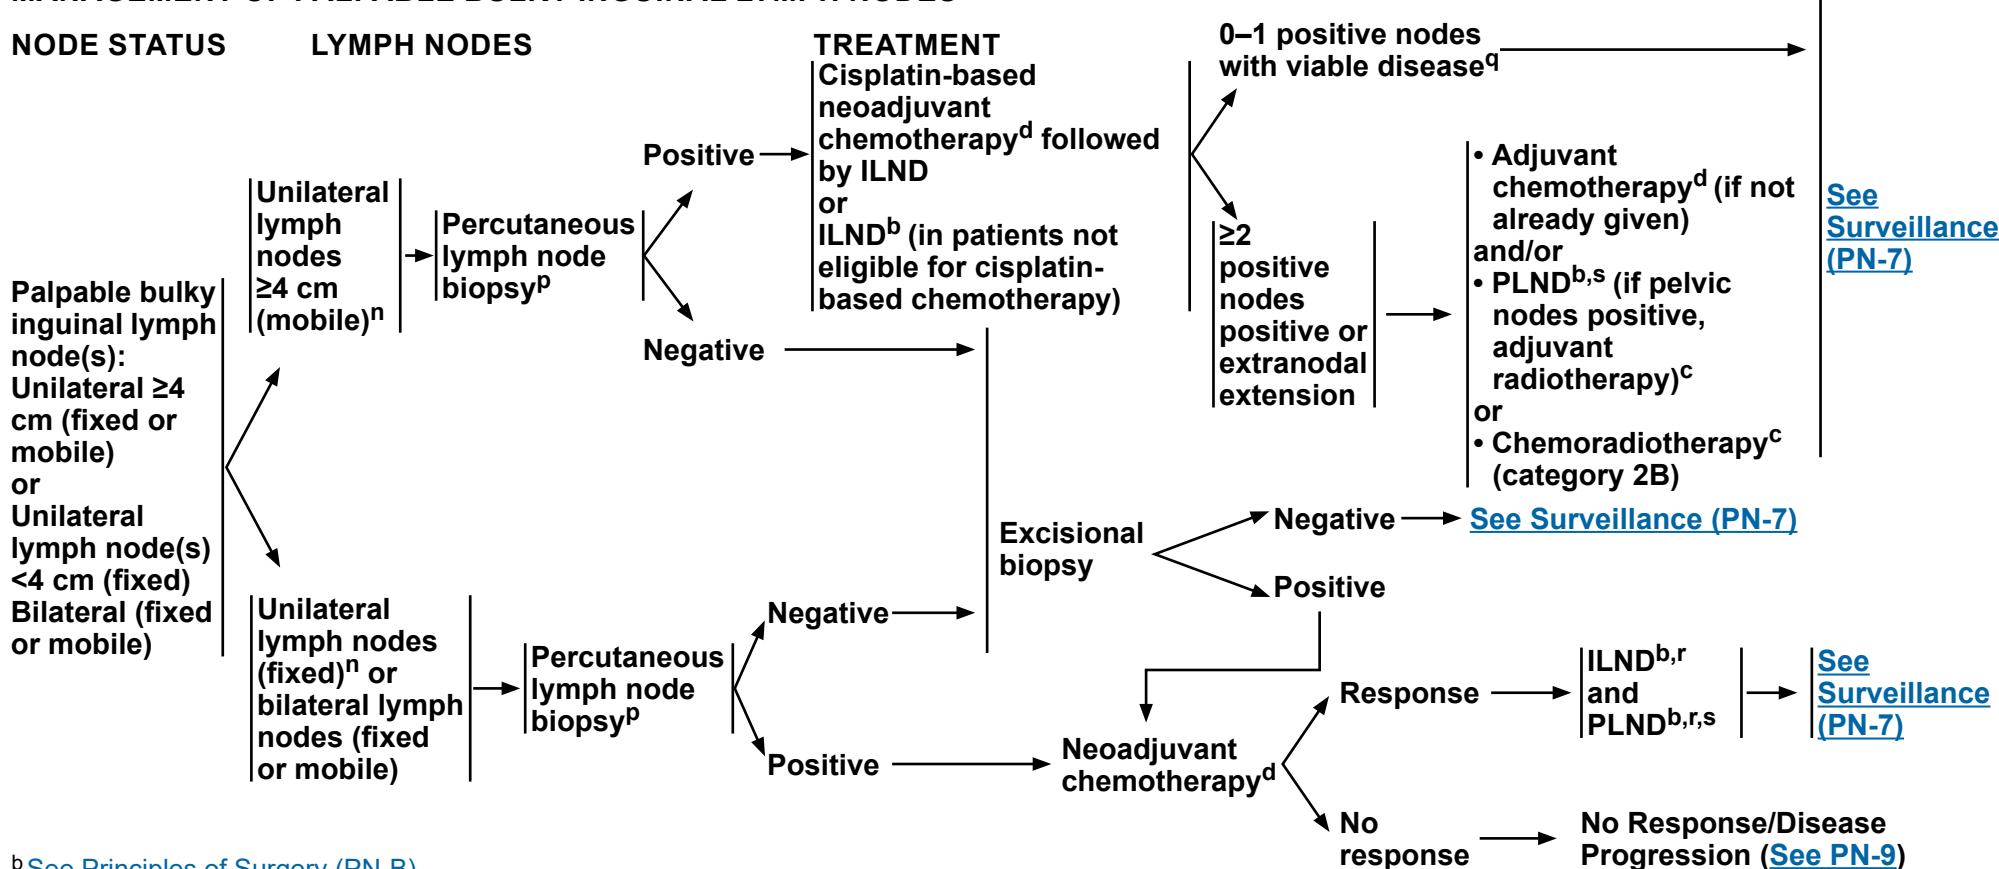

<sup>o</sup> High-risk primary lesion: T1, high-grade, lymphovascular invasion, >50% poorly undifferentiated.

<sup>p</sup> Ultrasound- or CT-guided biopsy.

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### MANAGEMENT OF PALPABLE BULKY INGUINAL LYMPH NODES

<sup>b</sup> See Principles of Surgery (PN-B).

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

<sup>n</sup> The size threshold of 4 cm represents the largest diameter of contiguous inguinal lymph node(s) tissue as measured on either physical examination and/or axial imaging (CT or MRI) and suspected of harboring metastatic disease.

<sup>p</sup> Ultrasound- or CT-guided biopsy.

<sup>q</sup> For viable disease post-chemotherapy, consider PLND.

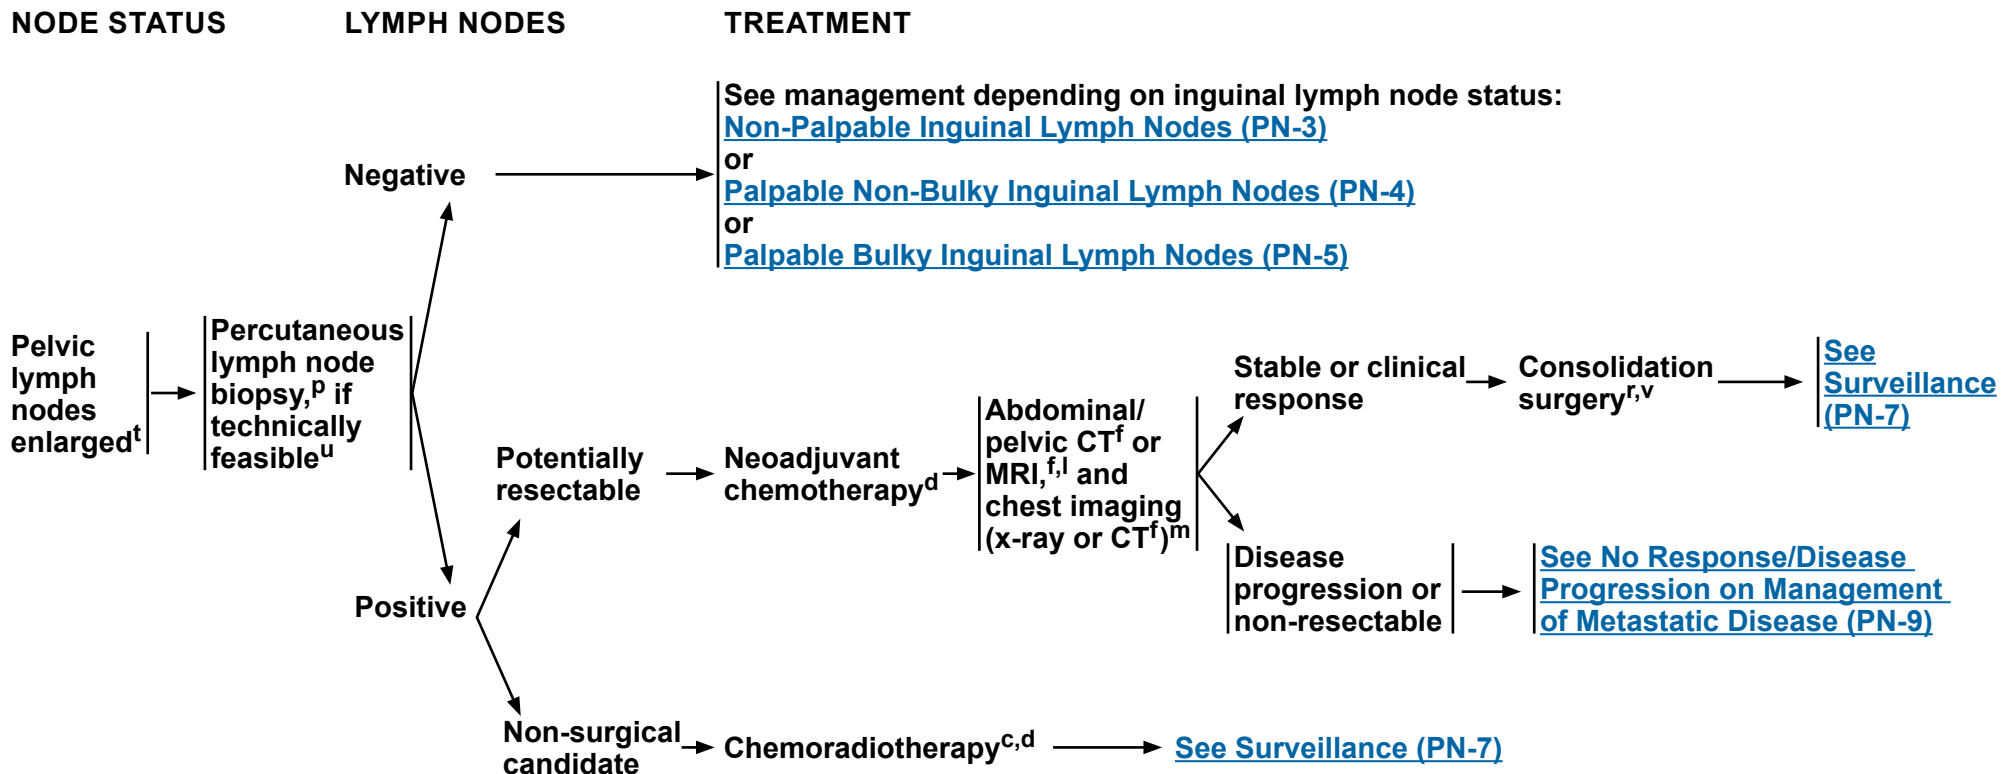

<sup>r</sup> Consider postoperative radiotherapy or chemoradiotherapy (category 2B).

<sup>s</sup> Data suggest that in the setting of ≥4 positive inguinal lymph nodes, bilateral PLND should be performed. Zargar-Shoshtari K, Djajadiningrat R, Sharma P, et al. Establishing criteria for bilateral pelvic lymph node dissection in the management of penile cancer: lessons learned from an international multicenter collaboration. J Urol 2015;194:696-701.

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### MANAGEMENT OF ENLARGED PELVIC LYMPH NODES

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

<sup>f</sup> With contrast unless contraindicated.

<sup>l</sup> Consider PET/CT scan (skull-base to mid-thigh).

<sup>m</sup> If M1 disease identified, see Management of Metastatic Disease (PN-9).

<sup>p</sup> Ultrasound- or CT-guided biopsy.

<sup>r</sup> Consider postoperative radiotherapy or chemoradiotherapy (category 2B).

<sup>t</sup> On CT or MRI, not pathologic stage.

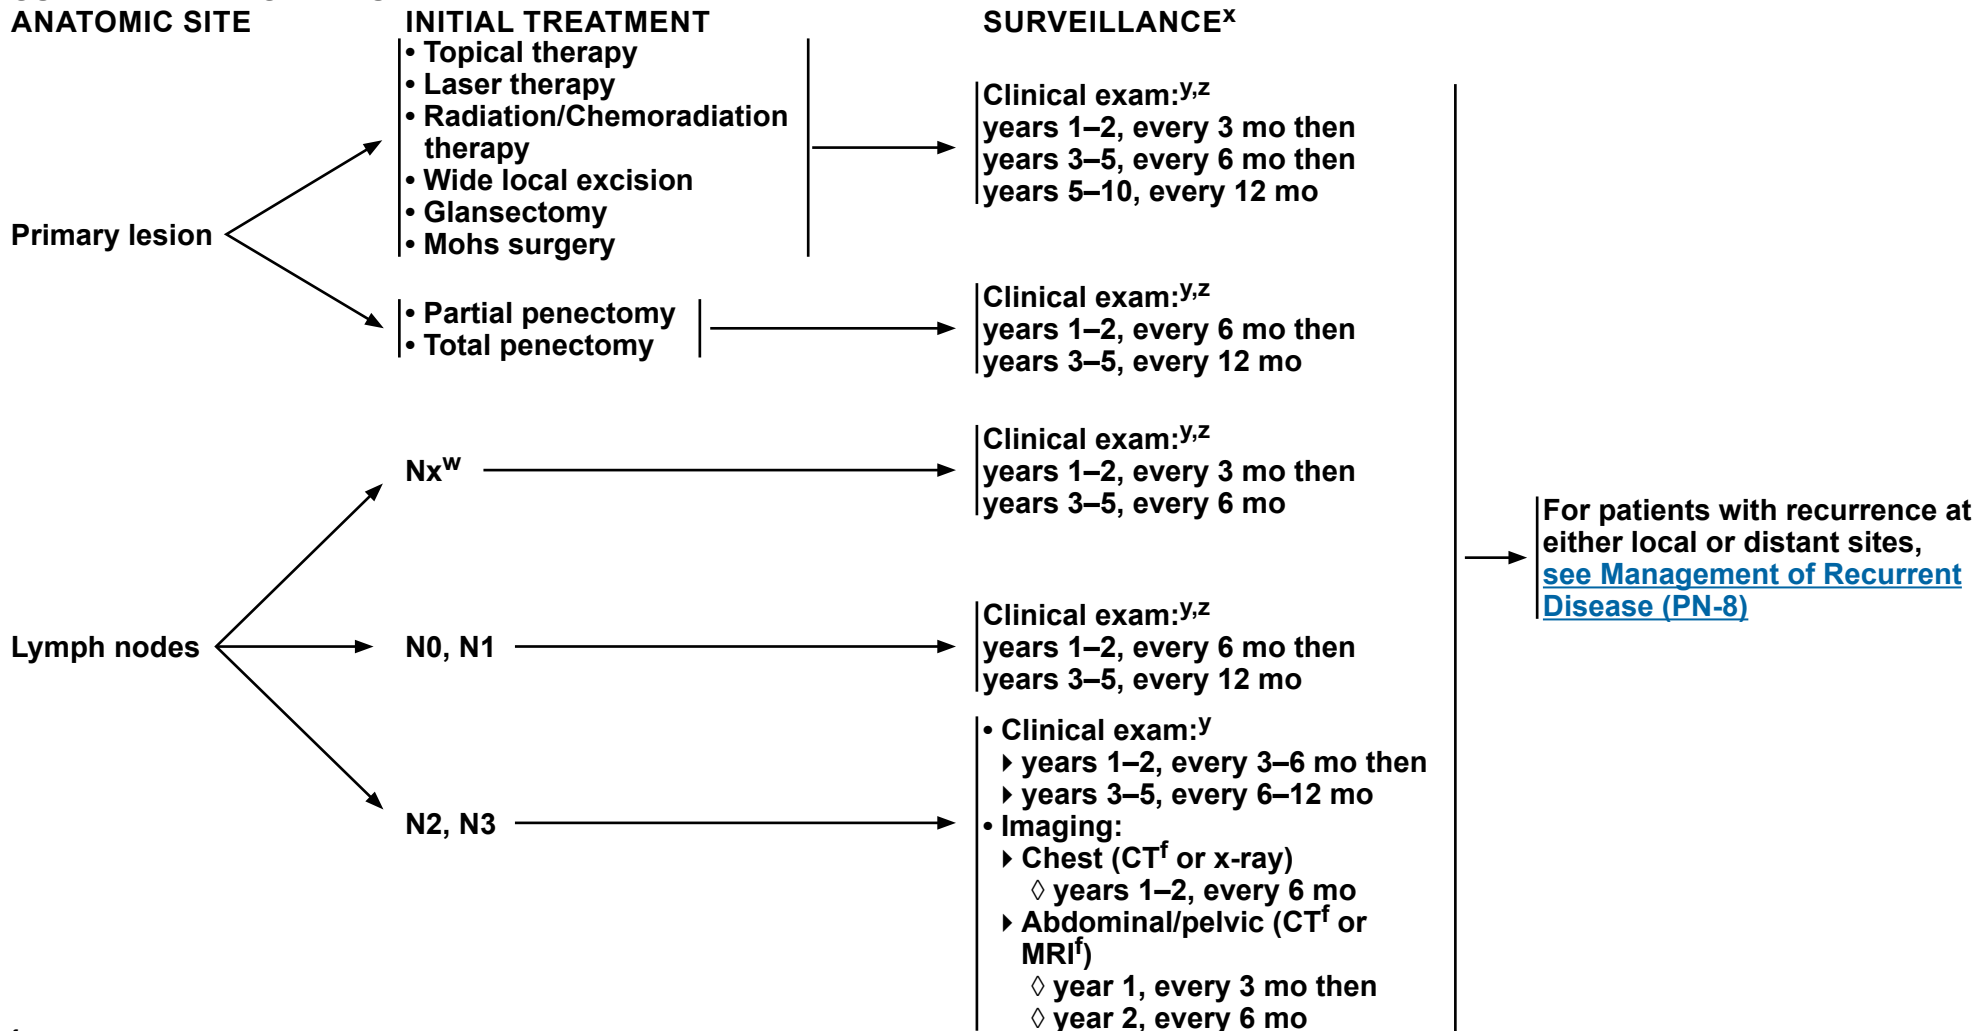

<sup>u</sup> If not technically feasible, PET/CT scan can be used to evaluate lymph nodes.

<sup>v</sup> Consolidation surgery consists of bilateral superficial and deep ILND and unilateral/bilateral PLND.

**Note: All recommendations are category 2A unless otherwise indicated.**

**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

### SURVEILLANCE SCHEDULE

<sup>f</sup> With contrast unless contraindicated.

<sup>w</sup> Patients on active surveillance of clinically negative nodes and at low risk for inguinal metastases.

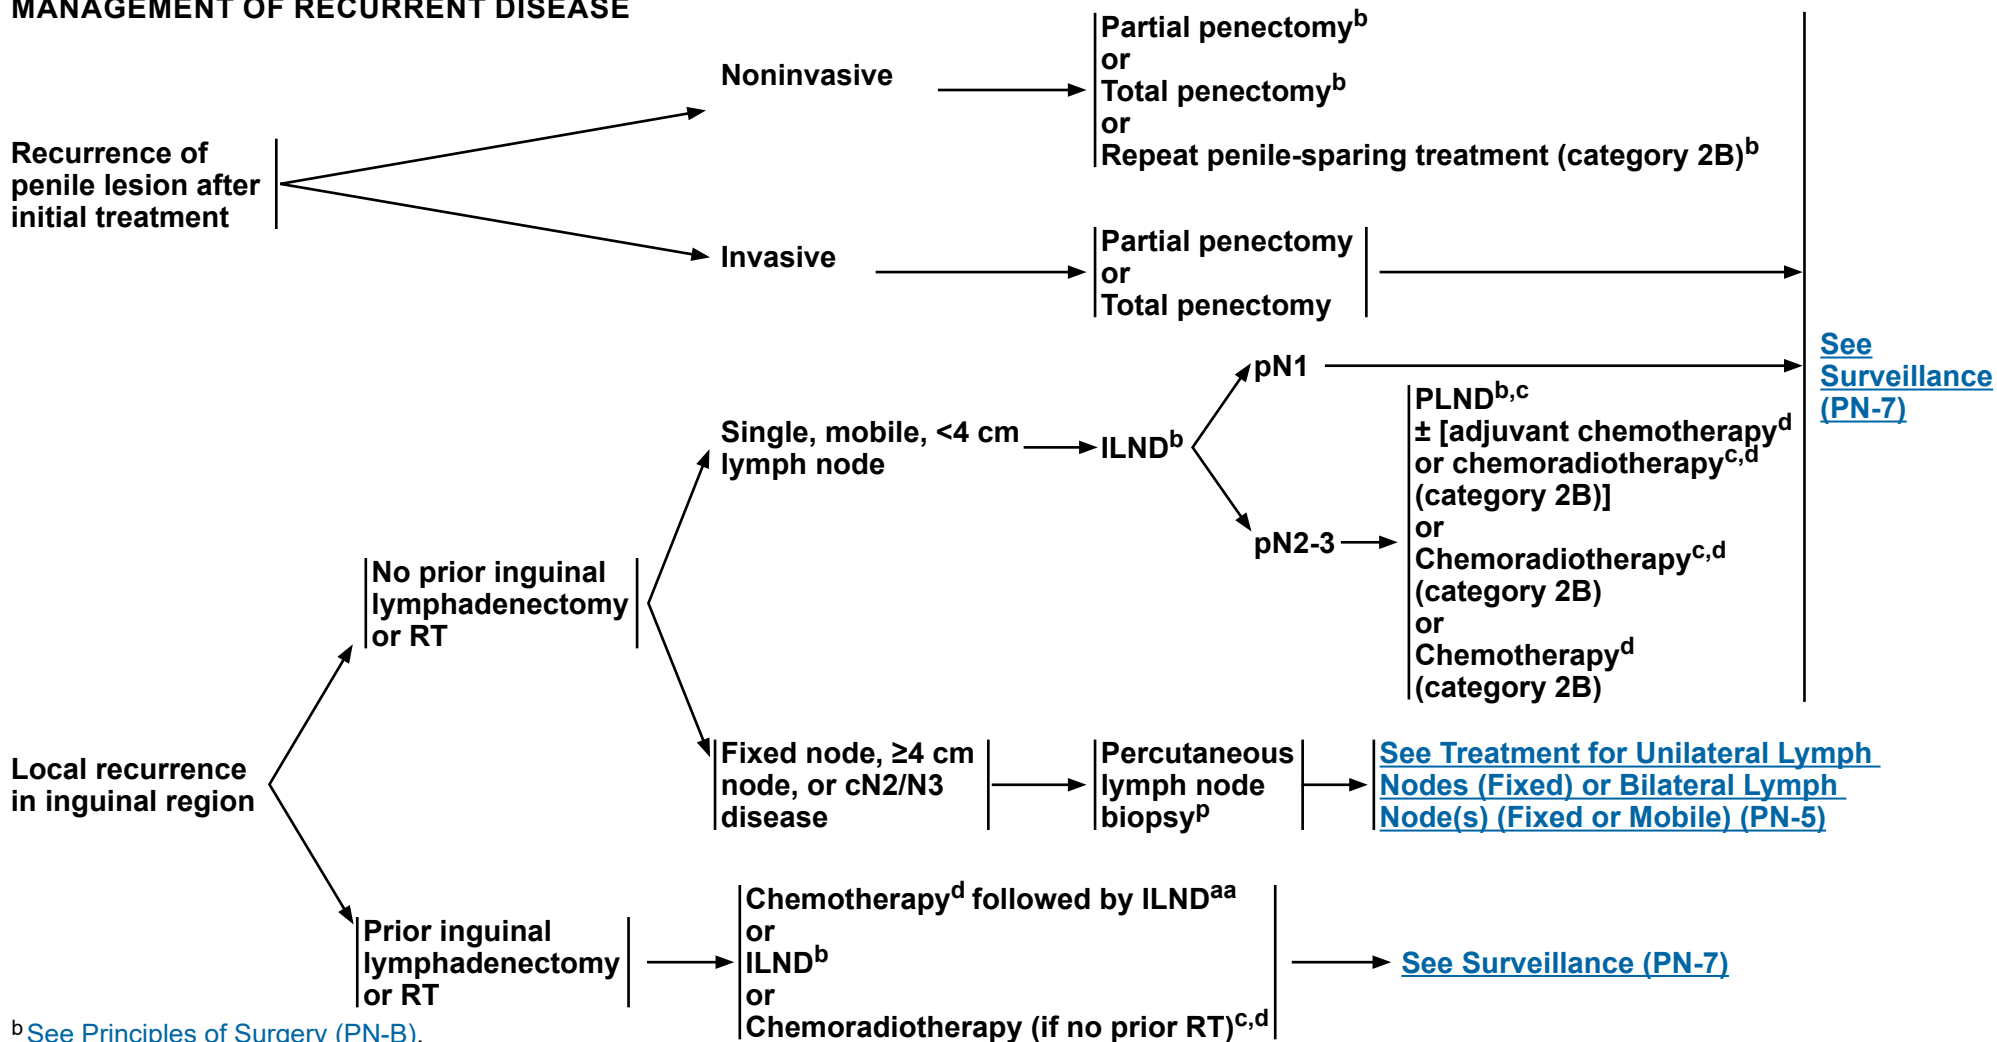

<sup>x</sup> See [NCCN Guidelines for Survivorship](#).

<sup>y</sup> Clinical exam includes examination of the penis and inguinal region.

<sup>z</sup> If an abnormal clinical exam, obese patient, or prior inguinal surgery, then ultrasound, CT with contrast, or MRI with contrast of the inguinal region can be considered.

**Note: All recommendations are category 2A unless otherwise indicated.**  
**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

### MANAGEMENT OF RECURRENT DISEASE

<sup>b</sup> See Principles of Surgery (PN-B).

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

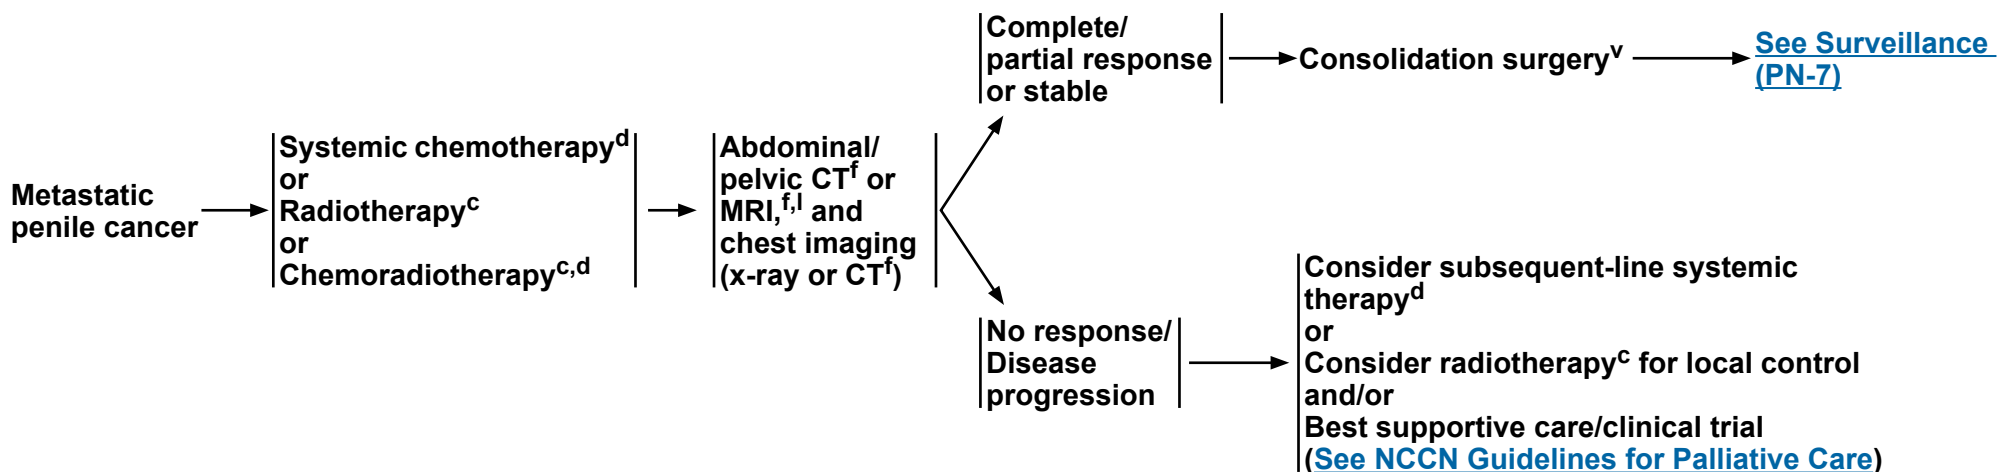

<sup>p</sup> Ultrasound- or CT-guided biopsy.

<sup>aa</sup> Baumgarten AS, Alhammali E, Hakky TS, et al. Salvage surgical resection for isolated locally recurrent inguinal lymph node metastasis of penile cancer: international study collaboration. J Urol 2014;192:760-764.

**Note: All recommendations are category 2A unless otherwise indicated.**

**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

### MANAGEMENT OF METASTATIC DISEASE

<sup>c</sup> See Principles of Radiotherapy (PN-C).

<sup>d</sup> See Principles of Systemic Therapy (PN-D).

<sup>f</sup> With contrast unless contraindicated.

<sup>l</sup> Consider PET/CT scan (skull-base to mid-thigh).

<sup>v</sup> Consolidation surgery consists of bilateral superficial and deep ILND and unilateral/bilateral PLND.

**Note: All recommendations are category 2A unless otherwise indicated.**

**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

### PRINCIPLES OF PENILE ORGAN-SPARING APPROACHES

Tis, Ta, and T1 penile cancer lesions may be amenable to conservative penile organ-sparing approaches, including topical therapy, wide local excision, laser therapy, glansctomy, and Mohs surgery.

#### Topical therapy<sup>1</sup>

- For patients with Tis or Ta disease:
  - ▶ Imiquimod 5%, apply at night three times per week for 4–16 weeks.
  - ▶ 5-FU cream 5%, apply twice daily for 2–6 weeks.

#### Laser therapy (category 2B)

- The use of therapeutic lasers (CO<sub>2</sub>, Nd:YAG, and KTP) to treat selected (clinical stage Tis, Ta, and T1 Grade 1–2) primary penile tumors has been reported with acceptable outcomes.
- Perioperative application of 3%–5% acetic acid to the potentially affected genital skin can be used to identify suspected sites of human papillomavirus (HPV)-infected skin that turns white upon exposure, making these acetowhite areas appropriately targetable for laser ablation.
- A plume (smoke) evacuator is required during penile laser treatments to minimize exposure to HPV and other viral particles as well as combustion-related carcinogens.
- The following is a table of the therapeutic lasers commonly used to treat penile cancer including suggested settings.

	<u>CO<sub>2</sub></u>	<u>Nd:YAG</u>	<u>KTP</u>
Type	Gas	Solid state	Solid state
Wavelength	10,600 nm	1,064 nm	532 nm
Tissue penetration	0.1 mm	3–4 mm	1–2 mm
Commonly used settings	Spot size: 1–5 mm Power: 5–10 W Pulse: Continuous or superpulse 100–200 Hz	Spot size: 1–5 mm Power: 40 W Pulse duration: 1 ms Pulse frequency: 10–40 Hz	Fiber size: 400 or 600 um Power: 5–10 W Pulse duration: 10–20 ms Repetition rate: 2 Hz

<sup>1</sup> McGillis ST1, Fein H. Topical treatment strategies for non-melanoma skin cancer and precursor lesions. *Semin Cutan Med Surg* 2004;23:174-183.

**Note:** All recommendations are category 2A unless otherwise indicated.  
**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

[Continued](#)

### PRINCIPLES OF PENILE ORGAN-SPARING APPROACHES

#### Wide Local Excision

- For early-stage penile cancer confined to the skin with little or no invasion (clinical stage Tis, Ta, T1).
- The surgical margins for wide local excision depend on the location of the penile tumor.
  - ▶ Penile tumors of the shaft may be treated with wide local excision, with or without circumcision.
  - ▶ Circumcision alone may be reasonable for tumors of the distal prepuce.
- Complete excision of the skin with a wide negative margin is needed and may require the use of a split-thickness skin graft (STSG) or full-thickness skin graft (FTSG) (if a primary tension-free reapproximation cannot be completed).
- If positive surgical margins, re-resection may be considered for low-grade disease.
- Glans resurfacing may be considered in highly select patients.

#### Glansectomy

- Glansectomy may be considered for select patients with distal tumors (clinical stage Ta, Tis, and T1) on the glans or prepuce.
  - ▶ For patients with Ta or Tis disease, a complete glansectomy is a category 2B recommendation.
  - ▶ For patients with T1 G1-2 disease, glansectomy is not recommended unless required to ensure complete tumor eradication with negative margins.
- Negative surgical margins should be determined from frozen sections of the cavernosal bed and urethral stump.
- Treatment is followed in certain instances with a STSG or FTSG to create a neoglans.

#### Mohs Micrographic Surgery (category 2B)

- Mohs surgery is an alternative to wide local excision in select cases.<sup>2</sup>
  - ▶ Thin layers of cancerous skin are excised and viewed microscopically until a tissue layer is negative for the tumor.
  - ▶ Allows for increased precision, though the success rate declines with higher stage disease.
- May be preferable for a small superficial lesion on the proximal shaft to avoid total penectomy for an otherwise fairly low-risk lesion.

<sup>2</sup> Shindel AW, Mann MW, Lev RY, et al. Mohs micrographic surgery for penile cancer: management and long-term followup. J Urol 2007;178:1980-1985.

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

## PRINCIPLES OF SURGERY

### Penectomy

- Partial penectomy should be considered the standard for high-grade primary penile tumors, provided that a functional penile stump can be preserved and negative margins are obtained. If a partial penectomy is not possible, a total penectomy should be performed.
- Partial or total penectomy when invasion into the corpora cavernosum is necessary to achieve a negative margin.
- Intraoperative frozen sections are recommended to determine negative margins.

### Surgical Management of Inguinal and Pelvic Lymph Nodes

- Standard or modified ILND or DSNB is indicated in patients with penile cancer in the absence of palpable inguinal adenopathy if high-risk features for nodal metastasis are seen in the primary penile tumor:
  - ▶ Lymphovascular invasion
  - ▶  $\geq pT1G3$  or  $\geq T2$ , any grade
  - ▶  $>50\%$  poorly differentiated
- DSNB is only recommended if the treating physician has experience with this modality.
- If positive lymph nodes are found on DSNB, ILND is recommended.
- PLND should be considered at the time or following ILND in patients with  $\geq 3$  positive inguinal nodes on the ipsilateral ILND site or in the presence of extranodal extension on final pathologic review.
- A bilateral PLND should be considered either at the time or following ILND in patients with  $\geq 4$  positive inguinal nodes (in total among both sides).<sup>1</sup>
- See [Discussion](#) for further details regarding ILND and PLND.

<sup>1</sup>Zargar-Shoshtari K, Djajadiningrat R, Sharma P, et al. Establishing criteria for bilateral pelvic lymph node dissection in the management of penile cancer: lessons learned from an international multicenter collaboration. J Urol 2015;194:696-701.

**Note: All recommendations are category 2A unless otherwise indicated.**

**Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.**

## PRINCIPLES OF RADIOTHERAPY

### T1-2, N0

If tumor <4 cm

- Circumcision followed by either:
  - ▶ Brachytherapy alone<sup>1,2</sup> (category 2B) (should be performed with interstitial implant);
  - or
  - ▶ External beam RT (EBRT) (category 2B): Total dose 65–70 Gy with conventional fractionation using appropriate bolus to primary penile lesion with 2-cm margins.
  - ▶ EBRT with concurrent chemotherapy (category 3):<sup>3</sup> Total dose 65–70 Gy with conventional fractionation using appropriate bolus to primary penile lesion with 2-cm margins.
  - ▶ Consider prophylactic EBRT to inguinal lymph nodes in patients who are not surgical candidates or who decline surgical management.

If tumor ≥4 cm

- Circumcision followed by either:
  - ▶ EBRT with concurrent chemotherapy (category 3):<sup>3</sup> 45–50.4 Gy to a portion of or whole penile shaft depending on bulk and extent of lesion plus pelvic/inguinal nodes, then boost primary lesion with 2-cm margins (total dose 65–70 Gy);
  - or
  - ▶ Brachytherapy alone (category 2B) in select cases and with careful post-treatment surveillance.

## Primary Radiation/Chemoradiation Therapy (Penile Preservation)

### T3-4 or N+ (surgically unresectable)

- Circumcision followed by:
  - ▶ EBRT with concurrent chemotherapy (category 3):<sup>3</sup> 45–50.4 Gy to whole penile shaft, pelvic lymph nodes, and bilateral inguinal lymph nodes, then boost primary lesion with 2-cm margins and gross lymph nodes (total dose 60–70 Gy).

### Primary Site Margin Positive Following Penectomy

- Postsurgical EBRT: If no gross disease: 45–60 Gy to the primary site and scar. If gross disease remains, follow guideline for T3-4, or N+.
- Treat bilateral inguinal lymph nodes and pelvic lymph nodes if no or inadequate lymph node dissection.
- Brachytherapy may be considered in select cases.

### Adjuvant Chemoradiotherapy

- Inguinal and/or pelvic lymph node positive
  - ▶ Recommended for palpable bulky inguinal lymph nodes or enlarged pelvic lymph nodes;<sup>3</sup> consider for palpable non-bulky inguinal lymph nodes pN2-3 disease (category 2B) or for local recurrence to inguinal region (category 2B).
  - ▶ Inguinal and pelvic lymph node EBRT to 45–50.4 Gy.
  - ▶ Boost gross nodes and areas of extracapsular extension to a total dose of 65–70 Gy.
  - ▶ Treat primary site of disease if positive margin.

<sup>1</sup> Crook J, Ma C, Grimard L. World J Urol 2009;27:189-196.

<sup>2</sup> de Crevoisier R, Slimane K, Sanfilippo N, et al. Int J Radiat Oncol Biol Phys 2009;74:1150-1156.

<sup>3</sup> For potential radiosensitizing agents and combinations, see [Principles of Systemic Therapy \(PN-D 2 of 4\)](#).

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

### PRINCIPLES OF SYSTEMIC THERAPY

Neoadjuvant Chemotherapy Prior to ILND or PLND
<b>Preferred Regimen</b>
• TIP (paclitaxel, ifosfamide, and cisplatin)

- Neoadjuvant chemotherapy with TIP (paclitaxel, ifosfamide, and cisplatin) is preferred (prior to ILND) in patients with ≥4 cm inguinal lymph nodes (fixed or mobile), if FNA is positive for metastatic penile cancer.<sup>1</sup>
  - ▶ Patients with initially unresectable (T4) primary tumors may be downstaged by response to chemotherapy.
- A Tx, N2-3, M0 penile cancer can receive 4 courses of neoadjuvant TIP. Stable or responding disease should then undergo consolidative surgery with curative intent. The phase II response rate was 50% in the neoadjuvant setting. The estimated rate of long-term progression-free survival for intent to treat was 36.7%. Improved progression-free and overall survival times were associated with objective response to chemotherapy.<sup>2</sup>

Adjuvant Chemotherapy Following ILND or PLND
<b>Preferred Regimen</b>
• TIP
<b>Other Recommended Regimen</b>
• 5-FU + cisplatin

- There are no sufficient data to form conclusions about the use of adjuvant chemotherapy. By extrapolation from the neoadjuvant data, it is reasonable to give 4 courses of TIP in the adjuvant setting if it was not given preoperatively and the pathology shows high-risk features. 5-FU plus cisplatin can be considered as an alternative to TIP in the adjuvant setting. ([See Management of Palpable Bulky Inguinal Lymph Nodes, PN-5](#)) Adjuvant EBRT or chemoradiotherapy can also be considered for patients with high-risk features.
- High-risk features include any of the following:
  - ▶ Pelvic lymph node metastases
  - ▶ Extranodal extension
  - ▶ Bilateral inguinal lymph nodes involved
  - ▶ 4-cm tumor in lymph nodes

**Note:** All recommendations are category 2A unless otherwise indicated.  
**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

[Continued](#)  
[References](#)

### PRINCIPLES OF SYSTEMIC THERAPY

<b>First-line Systemic Therapy for Metastatic/Recurrent Disease</b>
<b><u>Preferred Regimen</u></b>
• TIP
<b><u>Other Recommended Regimen</u></b>
• 5-FU + cisplatin

- **Not recommended:** Bleomycin-containing regimens are associated with unacceptable toxicity.<sup>3</sup>
- TIP is a reasonable first-line treatment for patients with metastatic penile cancer, including palliative treatment of patients with distant metastases.<sup>2</sup>
- 5-FU + cisplatin has been used historically for metastatic penile cancer and can be considered as an alternative to TIP.<sup>4</sup> It appears to be effective for some patients, although the toxicities may be limiting and require dose reductions.<sup>5</sup>
- There are no randomized clinical trials due to the rarity of penile cancer in industrialized countries.

<b>Subsequent-line Systemic Therapy for Metastatic/Recurrent Disease</b>
<b><u>Preferred Regimen</u></b>
• Clinical trial
• Pembrolizumab, if unresectable or metastatic, microsatellite instability-high (MSI-H) or mismatch repair-deficient (dMMR) tumor that has progressed following prior treatment and no satisfactory alternative treatment options <sup>6</sup>
<b><u>Useful in Certain Circumstances</u></b>
• Paclitaxel
• Cetuximab

- No standard subsequent-line systemic therapy exists.
- A clinical trial is preferred. The evidence to support the palliative use of second-line therapy is limited.<sup>7</sup>
- Paclitaxel<sup>8</sup> or cetuximab<sup>9</sup> may be considered in select patients, especially if not previously treated with a similar class of agent.

<b>Radiosensitizing Agents and Combinations<sup>10</sup> (Chemoradiotherapy)</b>
<b><u>Preferred Regimens</u></b>
• Cisplatin alone, or in combination with 5-FU
• Mitomycin C in combination with 5-FU
<b><u>Other Recommended Regimens</u></b>
• Capecitabine

**Note:** All recommendations are category 2A unless otherwise indicated.  
**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

## PRINCIPLES OF SYSTEMIC THERAPY

### Combination chemotherapy regimens

#### TIP<sup>2</sup> (preferred)

Paclitaxel 175 mg/m<sup>2</sup> IV over 3 hours on Day 1  
Ifosfamide 1200 mg/m<sup>2</sup> IV over 2 hours on Days 1–3  
Cisplatin 25 mg/m<sup>2</sup> IV over 2 hours on Days 1–3  
Repeat every 3 to 4 weeks

#### 5-FU + cisplatin<sup>4</sup> (not recommended for neoadjuvant setting)

Continuous infusion 5-FU 800–1000 mg/m<sup>2</sup>/d IV on Days 1–4 or  
Days 2–5  
Cisplatin 70–80 mg/m<sup>2</sup> IV on Day 1  
Repeat every 3 to 4 weeks

**Note:** All recommendations are category 2A unless otherwise indicated.

**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

## Discussion

### NCCN Categories of Evidence and Consensus

**Category 1:** Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2A:** Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.

**Category 2B:** Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.

**Category 3:** Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

**All recommendations are category 2A unless otherwise indicated.**

### NCCN Categories of Preference

**Preferred intervention:** Interventions that are based on superior efficacy, safety, and evidence; and, when appropriate, affordability.

**Other recommended intervention:** Other interventions that may be somewhat less efficacious, more toxic, or based on less mature data; or significantly less affordable for similar outcomes.

**Useful in certain circumstances:** Other interventions that may be used for selected patient populations (defined with recommendation).

**All recommendations are considered appropriate.**

## Overview

Squamous cell carcinoma (SCC) of the penis is a rare disease, representing 0.4% to 0.6% of all malignant neoplasms among men in the United States and Europe.<sup>1</sup> In 2019, the estimated number of new cases of penile and other male genital cancers in the United States is 2080, with 410 predicted cancer-specific deaths.<sup>2</sup> Incidence is higher (up to 10%) among men in the developing countries of Asia, Africa, and South America.<sup>3</sup> The most common age of presentation is between 50 and 70 years.<sup>4</sup> Early diagnosis is of utmost importance, as this is a disease that can result in devastating disfigurement and has a 5-year survival rate of approximately 50% (over 85% for patients with negative lymph nodes and 29%–40% for patients with positive nodes, with the lowest survival rates at 0% for patients with pelvic lymph node [PLN] involvement).<sup>5</sup> As the rarity of this disease makes it difficult to perform prospective, randomized trials, the NCCN Panel relied on the experience of penile cancer experts and the best currently available evidence-based data to collectively lay down a foundation to help standardize the management of this malignancy.

## Literature Search Criteria and Guidelines Update Methodology

Prior to the update of this version of the NCCN Guidelines for Penile Cancer, an electronic search of the PubMed database was performed to obtain key literature using the following search term: penile cancer. The PubMed database was chosen as it remains the most widely used resource for medical literature and indexes only peer-reviewed biomedical literature.<sup>6</sup>

The search results were narrowed by selecting studies in humans published in English. Results were confined to the following article

types: Clinical Trial; Guideline; Meta-Analysis; Randomized Controlled Trial; Systematic Reviews; and Validation Studies.

The data from key PubMed articles as well as articles from additional sources deemed as relevant to these guidelines and discussed by the panel have been included in this version of the Discussion section (eg, e-publications ahead of print, meeting abstracts). Recommendations for which high-level evidence is lacking are based on the panel's review of lower-level evidence and expert opinion.

The complete details of the Development and Update of the NCCN Guidelines are available at [www.NCCN.org](http://www.NCCN.org).

## Risk Factors

In the United States the median age of diagnosis is 68 years, with an increase in risk for males older than 50 years.<sup>7</sup> Early detection is assisted by the ability to do a good physical exam. Phimosis may hinder the capability to properly inspect the areas of highest incidence—the glans, inner preputial layer, coronal sulcus, and shaft. Men with phimosis carry an increased risk for penile cancer of 25% to 60%.<sup>4,8,9</sup> A review of penile SCC in the United States showed that 34.5% of patients had the primary lesion on the glans, 13.2% on the prepuce, and 5.3% on the shaft, with 4.5% overlapping and 42.5% unspecified.<sup>7</sup> Other risk factors include balanitis, chronic inflammation, penile trauma, lack of neonatal circumcision, tobacco use, lichen sclerosus, poor hygiene, and a history of sexually transmitted disease(s), especially HIV and human papillomavirus (HPV).<sup>4</sup> Overall, about 45% to 80% of penile cancers are related to HPV, with a strong correlation with types 16, 6, and 18.<sup>4,8,10-12</sup> While HPV infection is a risk factor for penile cancer, HPV- or p16-positivity have also been reported as favorable prognostic factors, in terms of better disease-specific survival (DSS).<sup>13,14</sup> There is

an 8-fold increased risk for patients with HIV, which may correspond to a higher incidence of HPV among males with HIV.<sup>15</sup>

Neonatal circumcision is associated with a lower rate of penile cancer, though the protective effect is not seen in adults who have the foreskin removed. This reduced incidence of penile cancer in patients who have been circumcised in infancy may reflect other known risk factors including the elimination of phimosis and lower incidence and duration of HPV infections in this population (reviewed by Morris et al<sup>16</sup>). A small study suggests that the benefits of circumcision may reduce invasive penile cancer but not carcinoma in situ (CIS, also called TIS).<sup>17</sup>

Cigarette smokers are noted to be 3 to 4.5 times more likely to develop penile cancer.<sup>10,18</sup> Patients with lichen sclerosus have a 2% to 9% risk of developing penile carcinoma.<sup>19-21</sup> Psoriasis patients undergoing psoralen plus ultraviolet A (PUVA) treatment have an increased penile cancer incidence of 286 times compared to the general population. Therefore, they should be shielded during treatment and any penile lesion should be closely monitored.<sup>22</sup> A study of men with advanced penile SCC receiving systemic therapy identified visceral metastases and an ECOG performance score greater than or equal to 1 as poor prognostic factors for both overall survival (OS) and progression-free survival.<sup>23</sup> However, studies remain limited on predictive factors of prognosis in this patient population.

## Clinical Presentation

Most often penile SCC presents as a palpable, visible lesion on the penis, which may be associated with penile pain, discharge, bleeding, or a foul odor if the patient delays seeking medical treatment. The lesion may be characterized as nodular, ulcerative, or fungating, and may be obscured by phimosis. The patient may exhibit signs of more advanced disease, including palpable nodes and/or constitutional symptoms (eg, fatigue, weight loss).

## Characterization and Clinical Staging

Approximately 95% of penile cancers originate in squamous epithelial cells and are further categorized as either SCC or penile intraepithelial neoplasia (PIN).<sup>24</sup> PIN is a premalignant condition at high risk of developing into SCC of the penis and includes the clinical entities of bowenoid papulosis, erythroplasia of Queyrat, and Bowen's disease.<sup>24</sup> The AJCC recognizes 4 subtypes of SCC: verrucous, papillary squamous, warty, and basaloid.<sup>25</sup> The verrucous subtype is considered to demonstrate low malignant potential, while other variants reported—adenosquamous and sarcomatoid variants—carry a worse prognosis.<sup>26,27</sup> The primary lesion is further characterized by its growth pattern with superficial spread, nodular or vertical-phase growth, and verrucous pattern. In addition to the penile lesion, evaluation of lymph nodes is also critical, as involvement of the inguinal lymph nodes (ILNs), the number and site of positive nodes, and extracapsular nodal involvement provide the strongest prognostic factors of survival.<sup>5,28</sup>

The AJCC TNM (tumor, node, and metastasis) Staging System for penile carcinoma has been used for staging, with the most recent update (eighth edition) published in 2017. It was initially introduced in 1968 and was subsequently revised in 1978, 1987, 2002, and 2010.<sup>29-33</sup> In 2010, the AJCC made the distinction between clinical and pathologic staging while eliminating the difference between superficial and deep inguinal metastatic nodes.<sup>29</sup> The eighth edition of the AJCC staging system<sup>25</sup> includes changes to the primary tumor (T) definitions, including: 1) broadening the Ta definition to include noninvasive localized squamous carcinoma; 2) describing T1 by the location of the tumor on the penis (eg, glans, foreskin, shaft) and defining invasion for each location; 3) adding perineural invasion as a prognostic indicator to define T1b from T1a; 4) including corpus spongiosum invasion within the T2 definition; and 5) including corpora cavernosum invasion within the T3 definition. In addition, the eighth edition includes changes to the

regional lymph node definitions, the most notable being pN1 defined as  $\leq 2$  unilateral inguinal metastases without extranodal extension and pN2 being defined as  $\geq 3$  unilateral inguinal metastases or bilateral metastases. Finally, stage II disease has been split into stage IIA and stage IIB with T1b or T2, N0, M0 defining stage IIA and T3, N0, M0 defining stage IIB<sup>25</sup> (see *Staging* in the algorithm).

The AJCC recommends a grading system for SCC of the penis based on the 3-tiered WHO/International Society of Urological Pathology (ISUP) grading system with the following definitions: grade 1, well differentiated; grade 2, moderately differentiated; and grade 3, poorly differentiated/undifferentiated. Any proportion of anaplastic cells categorizes the tumor as grade 3.<sup>25</sup> The overall degree of cellular differentiation with high-risk, poorly differentiated tumors is an important predictive factor for metastatic nodal involvement.<sup>34</sup> The AJCC also recommends collection of site-specific factors, including: the percentage of tumor that is poorly differentiated, the depth of invasion in verrucous carcinoma, the presence of lymphovascular or perineural invasion, the size of the largest lymph node metastasis, and the total number of lymph nodes removed.<sup>25</sup>

## Management of Primary Lesions

### Diagnosis

Evaluation of the primary lesion, regional lymph nodes, and distant metastasis will dictate the appropriate and adequate management of SCC of the penis, beginning with the first evaluation at presentation and then throughout follow-up. Vital to the initial management is a good physical exam of the penile lesion(s) that remarks on the diameter of the lesion(s) or suspicious areas; location(s) on the penis; number of lesions; morphology of the lesion(s); whether the lesion(s) are papillary, nodular, ulcerous, or flat; and the relationship with other structures including submucosal, urethra, corpora spongiosa, and/or corpora

cavernosa. To complete the initial evaluation, a histologic diagnosis with a punch, excisional, or incisional biopsy is paramount in determining the treatment algorithm based on a pathologic diagnosis.<sup>25,35,36</sup> This will provide information on the grade of the tumor, and will assist in the risk stratification of the patient for regional lymph node involvement.<sup>35,36</sup> MRI or ultrasound can be used to evaluate the depth of tumor invasion.<sup>37</sup> An ultrasound may also be considered for evaluation of ILNs that are difficult to assess. For the evaluation of lymph nodes, see *Management of Regional Lymph Nodes*.

### Penile Organ-Sparing Approaches

Tis, Ta, and T1 penile cancer lesions may be amenable to conservative penile organ-sparing approaches, including topical therapy, laser therapy, wide local excision, glansctomy, and Mohs surgery. An analysis of the National Cancer Database reported that OS rates were comparable for patients with pT1-T2 penile cancer that was treated with organ-sparing surgery compared to partial or total penectomy.<sup>38</sup> A multivariable model for predictors of patient survival in this study found that organ-sparing surgery did not predict poor patient survival (HR, 0.88; 95% CI, 0.64–1.21). Careful consideration should be given to penile-preserving techniques if the patient is reliable in terms of compliance with close follow-up.

#### *Topical Therapy*

Topical therapy is a valuable outpatient treatment due to ease of administration; however, patients should be monitored for adherence to therapy and for toxicity or adverse events. Local skin and application site reactions may occur and are generally mild to moderate, though severe reactions may occur with a higher frequency of application. Modification of the application frequency can resolve these complications. Despite significant response rates, the probability of relapse is higher following topical therapy than with other more

aggressive therapies. Therefore, patients who are eligible for topical therapy should be routinely monitored for recurrence.

While topical therapy for the treatment of PIN has been reported in numerous case studies and case reports, the data are limited by the small sample sizes and variation in treatment protocols. A retrospective review from a prospective database of patients diagnosed with PIN over a 10-year range identified patients who received either 5-fluorouracil (5-FU) as first-line therapy or imiquimod as the second-line topical agent.<sup>39</sup> Topical chemotherapy was given to 45 patients with a mean follow-up of 34 months. Therapy was standardized to 12 hours every 48 hours for 28 days. A complete response (CR) was reported in 25 patients (57%), while a partial response was seen in 6 patients (13.6%); no response was observed in the remaining 13 patients (29.5%). Following application of 5-FU, local toxicity and adverse events occurred in 10% and 12% of patients, respectively.<sup>39</sup> In another study, 5-FU treatment duration ranged from 3 to 7 weeks and was determined based on clinical response.<sup>40</sup> Out of 19 patients, 14 (73.7%) had a CR and none of the patients had recurrence at the median time of follow-up (3.5 years).<sup>40</sup> Topical 5-FU for 6 weeks has also reported good response rates at 5 years.<sup>41,42</sup>

Imiquimod has been investigated as a second-line therapy for PIN. Due to its ability to produce significant inflammation, initiation of imiquimod therapy at a lower frequency (eg, 2 times per week) may be beneficial to evaluate for toxicity or adverse events before increasing the frequency of application. Early studies suggested a 100% response to imiquimod (n = 47; 70% CR),<sup>43</sup> though a subsequent review identified a lower response to therapy with 63% of patients showing a CR and 29% of patients showing no response.<sup>44</sup> The study highlighted that the difference in response may be related to the frequency and duration of application as well as the PIN subtype. In this study, Bowenoid

papulosis and Bowen's disease subtypes responded better to imiquimod than the erythroplasia of Queyrat subtype. Longer, less frequent application (ie, fewer than 4 times per week for an average of 113 days) was demonstrated to have a better response than a shorter, more frequent application (ie, 4 times or more per week for an average of 53 days) (81% vs. 68%, respectively).

### **Laser Therapy**

Laser therapy in select patients with Tis, Ta, or T1 G1-2 penile cancer has reported acceptable outcomes (see *Principles of Penile Organ-Sparing Approaches* in the algorithm). Four types of therapeutic lasers have been used and include carbon dioxide, Nd:YAG, argon, and potassium titanyl phosphate (KTP) lasers. Nd:YAG and carbon dioxide lasers are the most commonly used, though KTP laser may also be considered. Nd:YAG lasers have the deepest penetration capability of 3 to 4 mm compared with the carbon dioxide laser that penetrates to a depth of 0.1 mm and KTP lasers that penetrate to 1 to 2 mm.

Retrospective studies of laser therapy reported local recurrence rates of around 18%, comparable to that of surgery, with good cosmetic and functional results.<sup>45,46</sup> Penoscopically controlled laser excision of TIS or T1 penile carcinoma in 224 patients compared outcomes based on primary treatment with excisional surgery for CIS or initially invasive flat tumors.<sup>45</sup> Reductive chemotherapy was given prior to surgery for exophytic lesions to broaden the indication of laser excision. Complete excision with adequate lateral margins was achieved in 221 patients and with adequate deep margins in 217 patients. The 10-year recurrence rate was 17.5% (95% CI, 16.4%–18.6%), and the 10-year amputation rate was 5.5% (range, 5.2%–5.7%).<sup>45</sup> In a subsequent study from this group, 56 patients with pT1 disease were treated with carbon dioxide laser therapy. There were 53 patients alive and disease free at a median follow-up of 66 months.<sup>47</sup> The 3 deaths in the study were the

result of unrelated and intercurrent disease. Among the 53 patients evaluated at follow-up, 13 had local recurrence and 2 had positive ILNs. The local recurrence correlated to positive margins.<sup>47</sup> Another study evaluated Nd:YAG laser treatment of patients with T1, T2 or CIS disease. Local recurrence was reported in 48% of patients, with recurrence elsewhere in the glans penis occurring in 20% of cases.<sup>48</sup> There were 10 cases of nodal metastases, of which 8 were in patients with T2 disease.<sup>48</sup> These data emphasize the greater benefit of laser therapy in CIS or T1 disease. A systematic review of studies using laser and light therapies for erythroplasia of Queyrat reported complete remission in 81.4%, 62.5%, and 58.3% of patients treated with carbon dioxide laser, methyl aminolevulinate photodynamic therapy, or aminolevulinic acid photodynamic therapy, respectively.<sup>49</sup>

### ***Glansectomy***

Glansectomy, removal of the glans penis, may be considered for patients with distal tumors (clinical stage Ta, Tis, T1) on the glans or prepuce. Negative surgical margins should be determined from frozen sections of the cavernosal bed and urethral stump. Treatment in certain instances may include a split- or full-thickness skin graft.

A retrospective study of 177 patients with SCC of the glans who received glansectomy and split-thickness skin graft had a 9.3% incidence of local recurrence (median follow-up, 41.4 months).<sup>50</sup> In total, 13 patients received treatment for operative complications and 18 patients (10.7%) died from penile cancer. An earlier retrospective study including 25 patients demonstrated a DSS of 92%.<sup>51</sup> Taken together, studies indicate a low level of recurrence.<sup>51-54</sup>

### ***Wide Local Excision***

For wide local excision, a complete excision of the skin with a wide negative margin with skin grafting is needed. Surgical margins depend on the location of the tumor. Penile tumors of the shaft may be treated

with wide local excision, with or without circumcision. Circumcision alone may be reasonable for tumors of the distal prepuce. Either a split-thickness skin graft or full-thickness skin graft may be considered. Emphasis is placed again on patient selection and close follow-up, as the 2-year recurrence rate may reach up to 50%.<sup>55</sup> Studies have shown that surgical margins of 5 to 10 mm are as safe as 2-cm surgical margins, and 10- to 20-mm margins provide adequate tumor control.<sup>56</sup>

### ***Mohs Surgery***

Mohs surgery is an alternative to wide local excision in select patients.<sup>57</sup> This technique removes thin layers of cancerous skin, which are evaluated microscopically until the tissue is negative for tumor. A retrospective study including 33 patients with SCC of the penis, ranging from T1S to T3 disease, reported outcomes for patients who were treated with Mohs surgery.<sup>58</sup> Follow-up data were available for 25 patients, of which 8 had local recurrence. Seven patients underwent repeat Mohs surgery while one patient received a penectomy. One patient in this study died of metastatic disease. Although precision is higher with Mohs surgery, the success rate declines with higher stage of disease. Therefore, Mohs surgery may have the greatest benefit for patients with a small superficial lesion on the proximal shaft to avoid penectomy for an otherwise fairly low-risk lesion.

## **NCCN Recommendations**

### ***Tis or Ta***

For patients with penile CIS or noninvasive verrucous carcinoma, penis-preserving techniques may be utilized, including topical imiquimod (5%) or 5-FU cream, circumcision and wide local excision, laser therapy (category 2B), complete glansectomy (category 2B), or Mohs surgery in select cases (category 2B). Among these, topical therapy<sup>59-61</sup> and excisional organ-sparing surgery<sup>62</sup> are the most widely used.

For topical therapy, NCCN recommends application of imiquimod 5% cream at night 3 times per week for 4 to 16 weeks. Topical 5% 5-FU cream should be applied twice daily for 2 to 6 weeks. Laser therapy for the treatment of primary penile tumors has demonstrated acceptable outcomes with a perioperative application of between 3% and 5% acetic acid. Following application of acetic acid to the affected genital skin, suspected sites of HPV-infected skin will turn white and can be targeted for laser ablation. Gas and solid-state lasers may be considered (see *Principles of Surgery* in the algorithm).

### **T1G1-2**

Careful consideration should be given to penile-preserving techniques if the patient is reliable in terms of compliance with close follow-up. These techniques include wide local excision,<sup>57</sup> glansectomy in select cases, Mohs surgery in select cases (category 2B), laser therapy (category 2B),<sup>63</sup> and radiation therapy (RT) (category 2B) delivered as brachytherapy with interstitial implant (preferred) or external beam radiation therapy (EBRT).<sup>64-68</sup> Circumcision should always precede RT to prevent radiation-related complications. In cases where a penile-preserving technique is not feasible based on the size or location of the tumor, partial penectomy may be appropriate.

### **T1G3-4 or T≥2**

These lesions typically require more extensive surgical intervention with partial or total penectomy depending on the characteristics of the tumor and depth of invasion.<sup>35,36</sup> Intraoperative frozen sectioning is recommended to achieve negative surgical margins. If the tumor encompasses less than half of the glans and the patient agrees to very close observation, then a more conservative approach such as wide local excision or glansectomy may be considered for patients with T1G3-4 diagnosis. The patient should understand that there is an increased risk for recurrence and potential for a repeat wide local

excision should a local recurrence be noted, provided there is no invasion of the corpora cavernosa.<sup>46,54</sup> A clear and frank discussion should be had with the patient that a partial or total penectomy will likely be required should a larger or more invasive lesion be present.

The tumor size is an important factor when choosing RT as treatment. As the average length of the glans is about 4 cm, this serves as a cutpoint to reduce the risk of undertreating cavernosal lesions. In a study of 144 patients with penile cancer restricted to the glans treated by brachytherapy, larger tumors, especially those larger than 4 cm, were associated with higher risk of recurrence.<sup>69</sup> A high, 10-year, cancer-specific survival rate of 92% was achieved in this series.

There was nonuniform consensus among NCCN panelists on the use of RT as primary therapy due to scant data. For T1G3-4 or T2 tumors smaller than 4 cm with negative nodes, brachytherapy with interstitial implant, EBRT alone (category 2B), or EBRT with chemotherapy (category 3) are treatment options after circumcision. Consider prophylactic ILN irradiation if selecting EBRT.

For tumors 4 cm or larger or if there is node-positive disease that is surgically unresectable, circumcision should be performed followed by EBRT combined with chemotherapy. Brachytherapy following circumcision may be appropriate in select cases of tumors 4 cm or larger, but careful monitoring is necessary as the risks of complications and failures increase.<sup>70</sup> Crook and colleagues reported a 10-year cause-specific survival of 84% in 67 patients with T1-2 (select cases of T3) penile lesions treated with primary brachytherapy.<sup>68</sup> A meta-analysis comparing the efficacy of brachytherapy and penectomy reported similar 5-year OS rates between these two treatments (76% for penectomy vs. 74% for brachytherapy; odds ratio [OR], 0.79; 95% CI, 0.64–0.98), although patients who underwent penectomy had higher 5-year local control rates (85% vs. 80%; OR, 0.72; 95% CI, 0.58–0.90)

and 5-year disease-free progression rates (77% vs. 72%; OR, 0.77; 95% CI, 0.63–0.93).<sup>71</sup> However, one must be cautious in interpreting from this that brachytherapy and penectomy offer equally effective oncologic outcomes being that selection criteria can affect the efficacy and suitability of these primary treatment options for the individual patients. Brachytherapy is not recommended following penectomy or partial penectomy but may be considered following wide local excision or excisional biopsy of small lesions. Brachytherapy should only be performed in centers with significant experience using this treatment modality.

Post-surgical RT to the primary tumor site may be considered for positive margins.

## Management of Regional Lymph Nodes

### Evaluation and Risk Stratification

The presence and extent of regional ILN metastases has been identified as the single most important prognostic indicator in determining long-term survival in men with invasive penile SCC.<sup>28</sup> Evaluation of the groin and pelvis is an essential component of the metastatic workup of a patient. The involvement of the ILN can be clinically evident (ie, palpable vs. nonpalpable), adding to the difficulty in management. Clinical exam for ILN involvement should attempt to evaluate and assess for palpability, number of inguinal masses, unilateral or bilateral localization, dimensions, mobility or fixation of nodes or masses, relationship to other structures (eg, skin, Cooper's ligaments), and edema of the penis, scrotum, and/or legs.<sup>72,73</sup> Crossover drainage from left to right and vice versa does occur and is reproducible with lymphoscintigraphy.<sup>5,74</sup> The physical exam should describe the diameter of node(s) or mass(es), unilateral or bilateral localization, number of nodes identified in each inguinal region, and the relationship to other structures, particularly with respect to the mobility

or fixation of the node(s) or mass(es) to adjacent structures and/or involvement of the overlying skin. Imaging for palpable disease by CT or MRI may be used to assess the size, extent, location, and structures that are in close proximity to the ILN, as well as the presence of pelvic and retroperitoneal lymph nodes and distant metastasis. CT and MRI are limited in patients with nonpalpable disease.<sup>72,75</sup> While studies have looked at the use of nanoparticle-enhanced MRI, PET/CT, and 18F-fluorodeoxyglucose (FDG) PET/CT, the small sample sizes require validation in larger prospective studies.<sup>76–80</sup> When considering one imaging modality to evaluate the stage of the primary lesion and lymph node status, MRI appears to be the best choice to enhance the physical exam in patients where the inguinal region is difficult to assess (eg, morbidity, previous chemotherapy/RT).<sup>76,81</sup>

Consideration needs to be given to whether or not the primary lesion demonstrated any adverse prognostic factors. If one or more of these high-risk features is present, then pathologic ILN staging must be performed. Up to 25% of patients with nonpalpable lymph nodes harbor micrometastases.<sup>82</sup> Therefore, several predictive factors have been evaluated for their ability to identify the presence of occult lymph node metastasis.<sup>55,83</sup> Slaton et al<sup>82</sup> concluded that patients with pathologic stage T2 or greater disease were at significant risk (42%–80%) of nodal metastases if they exhibited greater than 50% poorly differentiated cancer and/or vascular invasion, and therefore should be recommended to undergo an inguinal lymph node dissection (ILND).<sup>5,82</sup> These factors can then further define patients into low-, intermediate-, and high-risk groups for lymph node metastasis.<sup>26,84,85</sup> The European Association of Urology determined risk stratification groups for patients with nonpalpable ILNs, and validated this in both uni- and multivariate analyses of prognostic factors. Patients can be stratified based on stage and/or grade into risk groups based on the likelihood of harboring occult node-positive disease, with the low-risk group defined as patients with

Tis, Ta, or T1a disease; the intermediate group as those with T1b disease (lymphovascular invasion); and the high-risk group as those with T2 or G3/G4 disease.<sup>73,84</sup>

There is a paucity of data regarding the predictive value of lymph node removal. A singular study suggests that DSS following radical lymphadenectomy can be predicted by the lymph node count and lymph node density.<sup>86</sup> Removal of greater than or equal to 16 lymph nodes in patients with pathologic negative nodes was associated with a significantly longer DSS rate ( $P < .05$ ). Furthermore, the 5-year disease-free survival in patients with pathologic positive nodes was 81.2% in patients with lymph node density (defined as the number of positive nodes divided by the total number of lymph nodes removed) greater than 16% compared to 24.4% in patients with less than 16% lymph node density ( $P < .001$ ).<sup>86</sup> Although this study suggests that lymph node count and density may be useful in predicting DSS, a larger validation study is necessary to support these preliminary data.

### Dynamic Sentinel Node Biopsy

The work by Cabanas used lymphangiograms and anatomic dissections to evaluate the sentinel lymph node drainage for penile cancer with nonpalpable ILNs.<sup>87</sup> This technique has been shown to have false-negative rates as high as 25%; therefore, it is no longer recommended.<sup>73,88</sup> Advancements have been made with the dynamic sentinel node biopsy (DSNB) technique developed for penile cancer by the Netherlands Cancer Institute using lymphoscintigraphy and performed with technetium-99m–labeled nanocolloid and patent blue dye isosulfan blue.<sup>89,90</sup> Initially, this technique was associated with a low sensitivity and high false-negative rate (16%–43%).<sup>91–94</sup> Refinement of the technique to include serial sectioning and immunohistochemical staining of pathologic specimens, preoperative ultrasonography with and without fine-needle aspiration (FNA) cytology, and exploration of

groins in which no sentinel node is visualized on intraoperative assessment decreased the false-negative rate from 19% to only 5%.<sup>89,95,96</sup> Using FNA with ultrasound can increase the diagnostic yield in metastases greater than 2 mm in diameter.<sup>75,97</sup> Crashaw et al<sup>98</sup> used ultrasound with DSNB and noted improved accuracy in identifying patients with occult lymph node metastases. With modification of the NCI protocol, Hadway et al<sup>99</sup> were able to achieve a similar false-negative rate (5%) with an 11-month follow-up. An observational cohort study of 1000 patients treated between 1956 and 2012 suggests that DSNB can improve 5-year survival in patients with clinically node-negative groins.<sup>100</sup> Data in this study showed that patients treated prior to 1994 (the year DSNB was incorporated into treatment) had an 82% 5-year survival compared to the 91% 5-year survival seen in patients treated between 1994 and 2012 ( $P = .021$ ). However, there are several limitations of this study, including the possibility that improved staging resulted in more patients being grouped in a higher risk group. Therefore, incorporation of DSNB into treatment should be limited to centers with experience. Secondary to the technical challenges associated with DSNB, to be accurate and reliable, it is recommended that DSNB be performed at tertiary care referral centers where at least 20 procedures are done per year.<sup>89,101</sup> It should be noted that DSNB is not recommended in patients with palpable ILNs.<sup>72</sup>

### Inguinal Lymph Node Dissection

The most frequent sites of metastasis from penile cancer are the ILNs, typically presenting as palpable inguinal lymphadenopathy. The management of ILNs by ILND has been fraught with concerns of surgical morbidity.<sup>73,102</sup> Early treatment of lymph node involvement has been shown to have a positive impact on survival, except if the patient has bulky nodal spread or other sites of metastases.<sup>103,104</sup> Palpable lymphadenopathy at the time of diagnosis does not warrant an immediate ILND. Of the patients with palpable disease, 30% to 50% will

be secondary to inflammatory lymph node swelling instead of metastatic disease.<sup>83</sup> Although the distinction between reactive lymph nodes and metastatic disease has traditionally been done with a 6-week course of antibiotics, percutaneous lymph node biopsy is the favored approach among penile cancer experts for patients with palpable nodes.<sup>5,72</sup> An antibiotic course may still be used but is limited to the setting of an overlying infection.<sup>5,72,105</sup> Data on robotic ILND are limited, although a systematic review has reported that the robotic approach is safe and effective, with lower morbidity than open surgery when carefully selecting for patients with non-palpable or non-bulky inguinal nodes.<sup>106</sup>

The boundaries of the standard, full-template ILND (ie, Daseler's quadrilateral area) are: superiorly, the inguinal ligament; inferiorly, the fossa ovalis; laterally, the medial border of sartorius muscle; and medially, the lateral edge of adductor longus muscle.<sup>105</sup> Historically, it has been recommended to keep the patient on bed rest for 48 to 72 hours, especially after myocutaneous flaps or repair of large skin defects, although the necessity for this is debatable and not corroborated with rigorous scientific data. Closed suction drains are placed at surgery and are typically removed when drainage is less than 50 to 100 mL per day.<sup>105,107</sup> Consideration should be given to keeping the patient on a suppressive dose of an oral cephalosporin (or other gram-positive, broad-spectrum antibiotic) for several days to weeks postoperatively in an attempt to decrease the risk of wound-related issues and minimize the risk for overall complications. However, the data supporting this treatment approach are very limited.<sup>105</sup>

#### **Modified Template Lymphadenectomy**

In attempts to decrease the morbidity associated with standard ILND, a modified template lymphadenectomy has been proposed that uses a shorter skin incision, limiting the field of inguinal dissection by excluding the area lateral to the femoral artery and caudal to the fossa ovalis, with

preservation of the saphenous vein and elimination of the need to transpose the sartorius muscle while providing an adequate therapeutic effect. This technique is commonly reserved for patients with a primary tumor that places them at increased risk for inguinal metastasis but with clinically negative groins on examination.<sup>105,108</sup> The modified technique has shown a decrease in complications. Contemporary modified ILND should include the central and superior zones of the inguinal region, as these sections were not included in the dissection leading to a false-negative rate of 15%.<sup>109,110</sup> It is important to note that if nodal involvement is detected on frozen section, the surgical procedure should be converted to a standard, full-template lymphadenectomy. A standard full-template lymphadenectomy should be considered in all patients who have resectable inguinal lymphadenopathy. However, studies would favor neoadjuvant chemotherapy prior to proceeding with surgery, particularly in patients with bulky ILN metastases (ie, fixed nodes or nodal diameter  $\geq 3$  cm).<sup>111,112</sup> Generally, ILND is performed within 4 to 6 weeks following the completion of systemic chemotherapy to allow patient recovery while minimizing the risk of cancer progression post-chemotherapy.

#### **Delayed Inguinal Lymphadenectomy**

Since data exist that suggest men with clinically negative groins undergoing immediate ILND have better survival outcomes than men undergoing delayed ILND once their groins are clinically positive, it is recommended that in most circumstances men with high-risk penile tumors should undergo immediate ILND. However, patients with lower-risk tumors who are undergoing active surveillance or high-risk men who refuse immediate ILND may experience an inguinal nodal recurrence at some time point during follow-up. The median time to inguinal recurrence after treatment of the primary penile tumor is approximately 6 months, with 90% occurring by year 3 and 100% by year 5.<sup>113-115</sup>

### **Unilateral Versus Bilateral Lymphadenectomy**

In patients with high-risk features who do not have palpable lymph nodes, bilateral lymphadenectomy is generally performed, because it is not possible to predict the laterality of inguinal nodal metastasis based on the location of the tumor on the penis. Similarly, in patients who have a unilateral palpable node, about 30% will have contralateral positive nodes that are not palpable.<sup>116</sup> Therefore, bilateral lymphadenectomy should be considered the standard of care in patients undergoing immediate ILND for high-risk penile tumors or because of palpable nodes. When there is a delayed (>1 year after treatment of the primary penile tumor) inguinal recurrence of cancer, it is usually unilateral, and some authors have suggested that ipsilateral ILND is adequate while others have advocated for bilateral ILND in this circumstance.<sup>5</sup>

### **Pelvic Lymphadenectomy**

Approximately 20% to 30% of patients with positive ILNs will also have cancer within PLNs. Interestingly, penile tumors do not appear to metastasize to the PLNs without first affecting the inguinal node echelon (ie, no skip lesions).<sup>87,115</sup> Patients who have only one positive inguinal node have a risk of pelvic nodal involvement of less than 5% as reported by the Netherlands Cancer Institute.<sup>117</sup> The presence of cancer within the PLN is associated with a very poor 5-year survival rate that is typically less than 10%. Based on these prior reports, pelvic lymphadenectomy (resection of external iliac, internal iliac, and obturator lymph nodes) is recommended in patients with 3 or more positive ILNs and in the clinical context of high-grade cancer within the ILN pathologic specimen. Pelvic lymph node dissection (PLND) can be conducted during the same operative session as the ILND if the intraoperative frozen section is positive in 3 or more of the inguinal nodes (raising the importance of obtaining a lymph node count intraoperatively) or in a delayed staged fashion based on the pathologic features of the ILND specimen.<sup>118,119</sup>

One area of controversy is whether the PLND should be performed ipsilaterally or bilaterally in patients with unilateral positive ILNs. Data suggest that the number of positive ILNs identified at the time of dissection may direct clinicians to unilateral or bilateral dissection. In a single retrospective study, the presence of 4 or more positive ILNs supported bilateral PLND.<sup>106</sup> Unilateral PLND was recommended if 3 or fewer ILN metastases were identified and if there was no suspicion of contralateral pelvic lymphadenopathy on preoperative imaging or intraoperatively. Crossover (right to left or left to right) of inguinal to pelvic nodes has not been well-studied; hence, both approaches are feasible and left at the discretion of the surgeon based on case-specific characteristics.

### **Adjuvant Therapy Following Lymph Node Dissection**

#### **Chemotherapy**

A patient who presents with resectable bulky disease will rarely be cured with a single treatment modality. Consideration should be given to neoadjuvant chemotherapy if ILNs are greater than or equal to 4 cm. Patients who may benefit from surgical consolidation would be those who had stable, partial, or CR following systemic chemotherapy, thus increasing their potential for disease-free survival.<sup>111,112</sup> Pagliaro et al<sup>120</sup> performed a phase II clinical trial in 30 patients, with stage N2 or N3 (stage III or stage IV) penile cancer without distant metastases, receiving neoadjuvant chemotherapy with paclitaxel, ifosfamide, and cisplatin. In this series, 50% of patients were noted to have a clinically meaningful response, and 22 patients (73.3%) subsequently underwent surgery. There was an improved time to progression and OS associated with chemotherapy responsiveness ( $P < .001$  and  $P = .001$ , respectively), absence of bilateral residual tumor ( $P = .002$  and  $P = .017$ , respectively), and absence of extranodal extension ( $P = .001$  and  $P = .004$ , respectively) or skin involvement ( $P = .009$  and  $P = .012$ , respectively).

A retrospective analysis evaluated the benefit of adjuvant chemotherapy on OS of patients with positive PLN following lymph node dissection. Less than half of the patients in this multi-institutional study received adjuvant chemotherapy (36 out of 84). These patients were younger, had a less aggressive pathology, were less inclined to receive adjuvant radiation, and demonstrated less bilateral inguinal disease and more inguinal extranodal extension. The median OS was higher for these patients compared to patients who did not receive adjuvant chemotherapy (21.7 months vs. 10.1 months;  $P = .021$ ). Adjuvant chemotherapy was further shown to be an independent factor in the improved OS based on multivariate analysis (HR, 0.40; 95% CI, 0.19–0.87;  $P = .021$ ).<sup>121</sup> Therefore, patients with positive PLN following surgical resection may benefit from adjuvant radiation or systemic chemotherapy.

### **Radiotherapy**

A multicenter, retrospective analysis evaluated the benefit of adjuvant pelvic radiation on OS and disease recurrence in 92 patients with positive PLN following PLND. Patients who received adjuvant pelvic radiation ( $n = 40$ ) had a longer median DSS than those who did not receive radiation (14.4 months vs. 8 months;  $P = .023$ ). Additionally, patients who did not undergo adjuvant radiation had worse OS (HR, 1.7; 95% CI, 1.01–2.92;  $P = .04$ ) and DSS (HR = 1.9; 95% CI, 1.09–3.36,  $P = .02$ ).<sup>122</sup>

Studies investigating the role of adjuvant radiation for positive lymph nodes following ILND have been mixed. A retrospective analysis of National Cancer Database records showed improved OS with adjuvant RT following ILND for stage III penile cancer (HR, 0.58, 95% CI, 0.39–0.86). Patients with higher nodal burden of disease showed greater benefit from adjuvant radiation.<sup>123</sup> On the other hand, a systematic review by the European Association of Urology Penile Cancer

Guidelines Panel reported that the few studies comparing recurrence and survival between patients who did or did not receive adjuvant radiotherapy after ILND for lymph-node positive disease received no significant benefit from the adjuvant radiotherapy.<sup>124</sup> Therefore, adjuvant radiotherapy is recommended following a PLND after a positive result on ILND.

### **Chemoradiotherapy**

Chemoradiotherapy has demonstrated improved responses in patients with other SCCs, specifically patients with vulvar and anal cancer.<sup>125-128</sup> Anecdotal data for the use of chemoradiotherapy in patients with penile cancer have been reported with mixed results.<sup>129-132</sup> Based on the limited data, chemoradiotherapy is a treatment option in select patients.

For patients with T1 or T2 disease, EBRT with concurrent chemotherapy may be considered though brachytherapy is preferred for tumors less than 4 cm. Similarly, EBRT with concurrent chemotherapy can be used for T3 or T4 disease or in patients with nodal involvement. Postoperative adjuvant chemotherapy is recommended in ILN-positive patients. Chemoradiotherapy can be considered for patients with high-risk features including PLN metastases, extranodal extension, bilateral ILN involvement, and tumors in lymph nodes larger than 4 cm.

Chemoradiotherapy is a recommended strategy for patients with resistant disease. The use of chemoradiotherapy as primary treatment is a category 3 recommendation due to the limited studies that have investigated its role for treatment of penile cancer. For patients with palpable, non-bulky pN2 or pN3 disease, treatment may entail adjuvant RT, chemoradiotherapy, or chemotherapy following ILND or PLND. Chemoradiotherapy is recommended for the management of enlarged PLNs in non-surgical candidates or for local recurrence in the inguinal region or metastatic penile cancer.

## NCCN Recommendations

### ***Nonpalpable Nodes***

Most low-risk patients (Tis, Ta, T1a) are followed with a surveillance protocol, as the probability of occult micrometastases in ILNs is less than 17%.<sup>84,114</sup> If positive lymph nodes are found on DSNB, ILND is recommended. For patients at intermediate (T1bG1-2) or high (T1bG3-4, T2 or greater) risk, a modified or radical inguinal lymphadenectomy is strongly recommended as occult metastatic disease ranges between 68% and 73%.<sup>55,84,114</sup> If positive nodes are present on the frozen section, then a superficial and deep inguinal lymphadenectomy should be performed (with consideration of a PLND). Prophylactic EBRT (category 2B) to the ILNs should be considered in patients who are unable or unwilling to undergo surgical management. Alternatively, DSNB can be considered.

As DSNB is currently not widely practiced in the United States, this technique should be performed in tertiary care referral centers with substantial experience. DSNB is not recommended for Ta tumors, as observation alone of the ILNs is sufficient for these well-differentiated lesions in the absence of palpable adenopathy.

### ***Unilateral Palpable Nodes <4 cm (mobile)***

Percutaneous lymph node biopsy is considered standard for these patients if no risk feature is present in the primary lesion. Risk features include T1 tumors; high grade; lymphovascular invasion; and poor differentiation in more than half of the tumor cells. The NCCN Panel recommends omitting the procedure for patients with high-risk primary lesions to avoid delay of lymphadenectomy. A negative lymph node biopsy should be confirmed with an excisional biopsy. Alternatively, careful surveillance may be considered following a negative lymph node biopsy. Positive findings from either procedure warrant an immediate ILND. Additionally, in cases of pN2-3 disease, a PLND with or without

adjuvant radiation, chemotherapy (category 2B), or chemoradiotherapy (category 2B) is recommended. Alternatively, chemoradiotherapy or chemotherapy alone may be given (both are category 2B recommendations). Following treatment, all patients should enter active surveillance.

### ***Unilateral Palpable Nodes ≥4 cm (mobile)***

Large, unilateral, mobile nodes should first be confirmed by percutaneous lymph node biopsy. A negative biopsy should be confirmed by an excisional biopsy. If results are negative again, the patient should be closely followed. Patients with confirmed nodes are amenable to standard or modified ILND. Neoadjuvant cisplatin-based chemotherapy is recommended before surgery, although ILND can be performed without neoadjuvant therapy in patients who are not eligible for cisplatin-based chemotherapy. No further treatment is necessary if no viable tumor elements are detected in the surgical specimen. Patients with viable disease in a single node after undergoing systemic chemotherapy can be considered for a PLND, but the evidence supporting this approach is sparse. If 2 or more positive nodes or extranodal extension is detected, adjuvant chemotherapy (if not already given) and/or PLND, with adjuvant radiation if PNLs are positive, is recommended. Alternatively, adjuvant chemoradiotherapy may be given (category 2B). Data suggest that in the setting of 4 or more positive ILNs, a bilateral PLND should be performed.<sup>133</sup> Postoperative RT or chemoradiotherapy may be considered in patients after PLND, particularly in the setting of a positive surgical margin, viable cancer in multiple ILNs or PLNs, and/or presence of extranodal extension on the final pathologic specimen.

### ***Unilateral Fixed Lymph Nodes or Bilateral Palpable Nodes (fixed or mobile)***

In the case of large, unilateral, fixed nodes or bilateral ILNs, patients should undergo a percutaneous lymph node biopsy of the lymph nodes.

A negative result should be confirmed with excisional biopsy. If results are again negative, the patient should be closely followed. Patients with a positive aspiration or biopsy should receive neoadjuvant systemic chemotherapy followed by ILND and PLND if there is a response to the chemotherapy. Postoperative RT or chemoradiotherapy may be considered (category 2B). As previously mentioned, in the setting of 4 or more positive ILNs, a bilateral PLND should be performed.<sup>133</sup> If the patient's disease does not respond to neoadjuvant chemotherapy, treatment may follow options for progressive metastatic disease.

### ***Enlarged Pelvic Lymph Nodes***

Patients with abnormal PLNs on imaging (CT or MRI) should proceed to a percutaneous lymph node biopsy if technically feasible. If positive, patients are stratified by resectability. Nonsurgical candidates should be treated with chemoradiotherapy. Patients with resectable disease should receive neoadjuvant systemic chemotherapy with consideration of a confirmatory percutaneous biopsy or PET/CT. Patients with disease that responds to therapy or that becomes stable should undergo bilateral superficial and deep ILND and unilateral/bilateral PLND if deemed resectable. Postoperative RT or chemoradiotherapy should be considered (category 2B). Patients with disease that progresses may receive additional systemic chemotherapy with consideration of local-field radiation or participation in a clinical trial.

### **Surveillance**

Initial treatment of the primary tumor and lymph nodes dictates the follow-up schedule (see *Surveillance Schedule* in the algorithm). A large retrospective review of 700 patients found that penile-sparing therapies carry a significantly higher risk of local recurrence (28%) than partial or total penectomy (5%) and thus require closer surveillance.<sup>115</sup> Patients without nodal involvement had a regional recurrence rate of 2%

compared to 19% for patients with node-positive disease. Of all recurrences, 92% were detected within 5 years of primary treatment.

Follow-up for all patients includes a clinical exam of the penis and inguinal region. Imaging is not routinely indicated for early disease (except for obese patients or patients who have undergone inguinal surgery since a physical exam may be challenging), but may be used upon abnormal findings. For patients with N2 or N3 disease, imaging of the chest, abdomen, and pelvic area is recommended.

### **Recurrence**

Invasive disease is an adverse finding after initial organ-sparing treatment that warrants partial or total penectomy.<sup>134,135</sup> For non-invasive primary tumor recurrences, repeat penile-sparing options can be considered (category 2B).

A recurrence in the inguinal region carries a poor prognosis (median survival, <6 months) and optimal management remains elusive. If no prior inguinal lymphadenectomy or RT was given, primary treatment for the management of ILNs can be followed. If the patient previously received lymphadenectomy or RT, subsequent-line therapies include chemotherapy followed by ILND, ILND alone, or chemoradiotherapy (if no prior RT).<sup>72,136</sup> A recent study suggests that ILND may be beneficial in patients with penile cancer with locally recurrent ILN metastases.<sup>137</sup> While potentially curative, patients must be advised of the high incidence of postoperative complications.<sup>137</sup>

### **Metastatic Disease**

Imaging of the abdomen and pelvis should be obtained when metastasis is suspected to evaluate for pelvic and/or retroperitoneal lymph nodes. PLN metastasis is an ominous finding, with a 5-year survival rate of 0% to 66% for all cases and 17% to 54% for microscopic

invasion only, with a mean 5-year survival of approximately 10%.<sup>5,138-142</sup> In patients with ILN metastases, 20% to 30% will have PLN metastases.<sup>5</sup> This can be further characterized such that if 2 to 3 ILNs are involved, there is a 23% probability of PLN involvement. With involvement of 3 or more ILNs, this probability increases to 56%.<sup>143</sup>

Lughezzani et al<sup>118</sup> identified 3 independent predictors of PLN metastases that included the number of inguinal metastases (OR, 1.92;  $P < .001$ ), the diameter of the metastases (OR, 1.03;  $P = .001$ ), and extranodal extension (OR, 8.01;  $P < .001$ ). Similar to previous studies, patients with 3 or more ILN metastases had a 4.77-fold higher risk of PLN metastasis. An ILN metastasis diameter of 30 mm or greater correlated with a 2.53-fold higher risk of PLN metastasis. Patients who showed no risk factors had a 0% risk of metastasis, suggesting that this group may not require PLND.<sup>118</sup>

Pettaway et al<sup>144</sup> evaluated the treatment options for stage IV penile cancer—clinical stage N3 (deep inguinal nodes or pelvic nodes) or M1 disease (distant metastases)—including chemotherapy, RT, and inguinal lymphadenectomy. Cisplatin-based regimens (paclitaxel, ifosfamide, and cisplatin or alternatively 5-FU plus cisplatin) are the most active first-line systemic chemotherapy regimens.<sup>36,120,145</sup> A retrospective analysis of 30 patients with non-metastatic N2 or N3 penile cancer who received neoadjuvant cisplatin-based chemotherapy as first-line treatment demonstrated a poor response to treatment when disease progressed (median OS <6 months).<sup>146</sup>

Systemic chemotherapy, RT, or chemoradiotherapy may be considered for the treatment of metastatic disease. The panel did not recommend regimens containing bleomycin because of high pulmonary-related toxicity.<sup>147</sup> Patients with a proven objective response to systemic chemotherapy are amenable to consolidative ILND with curative potential or palliation. However, surgical consolidation should not be

performed on patients with disease that progresses during systemic chemotherapy except for local symptomatic control. Preoperative RT may also be given to patients who have lymph nodes greater than or equal to 4 cm without skin fixation to improve surgical resectability and decrease local recurrence. For patients with unresectable inguinal or bone metastases, RT may provide a palliative benefit after chemotherapy. Systemic therapy may also be considered upon disease progression. The NCCN Panel strongly recommends consideration of clinical trial participation as data are limited in the second-line setting. However, in select patients, paclitaxel<sup>148</sup> or cetuximab<sup>149</sup> may be considered, especially if previous treatments did not include a similar class of agent. Pembrolizumab is preferred in the second-line setting for patients with microsatellite instability-high (MSI-H) or mismatch repair-deficient (dMMR) penile cancers.<sup>150</sup> Best supportive care remains an option for advanced cases or cases refractory to systemic therapy, RT, or chemoradiotherapy.

## Summary

SCC of the penis is a disease that mandates prompt medical/surgical intervention and patient compliance to obtain the most favorable outcomes. A thorough history and physical is the initial step in this process, followed by a biopsy of the primary lesion to establish a pathologic diagnosis. Accurate clinical staging allows for a comprehensive treatment approach to be devised, thus optimizing therapeutic efficacy and minimizing treatment-related morbidity. Prognostic factors help predict if lymph node metastases are suspected in the absence of any palpable inguinal lymphadenopathy. When clinically indicated, an ILND has curative potential, particularly when performed early, with contemporary surgical series demonstrating its reduced morbidity.
